INDEX TO VOLUME II., 1935.

32

REFERENCES AND ABBREVIATIONS

search of a given subject will find it useful to bear in mind that the references are in several distributed under two or more separate but nearly synonymous headings. Institutions orporations with the right to the prefix Royal will be found under that prefix, with the on of Hospitals, which will be found under that heading; and Medical Societies, which parately indexed under Societies. All Universities are indexed under the word Uni- (A) = Annotation, (C) = Correspondence, (LA) = Leading Article, (ML) = Medico-legal, New Inventions, (O) = Obituary, (PI) = Parliamentary Intelligence, (R) = Review, (PCP) = Panel ntract Practice, and (P) = Prognosis Series.

rdance of page numbers and dates of issue will be found on page xxvi.

ADDRESSES AND ORIGINAL ARTICLES

A CLINICAL STUDY OF HEADACHES *

BY SIR EDMUND SPRIGGS, K.C.V.O., M.D.,
F.R.C.P. Lond.
SENIOR PHYSICIAN, RUTHIN CASTLE

IN the early days of our lives as doctors we form impressions which lead us to become sceptical or sanguine about different cases. Our desire and hope is to do good to the patient, and, as he unfolds his story, there arises in the mind of the listener an estimate, built on heaped-up experience, of how far and in what way that hope can be fulfilled. When I was a student, there were a good many physicians who were by habit sceptical of the benefits of treatment generally. I was never one of them, but confess, as we all must, that there were certain groups of cases, which now can often be relieved, whose treatment was undertaken without much expectation of benefit. Among these were the sufferers from habitual headache. So many headaches were regarded as chronic, recurrent, familial, or due to the nervous make-up of the subject, that they seemed to be evils to be borne, with such alleviation as a few simple medicines could afford, rather than a field for active inquiry and treatment.

It is usual and convenient in teaching or speaking of systematic medicine to treat of diseases. But in practice one is confronted with symptoms. Headache is a symptom. It may arise from many different causes and is a frequent complaint in all branches of medical work. The sum total of its effects must be enormous, in pain, in limiting the power of the sufferers, in the shirking of issues and the loss of pleasures. The depressing and limiting effects upon those around are also great. Sometimes a headache is so intense that it fills the whole field, is, indeed, the disease. Often it is, though distressing, more bearable, and at other times it appears to call for or receive little attention. It cannot be admitted that symptoms, or other phenomena, vary in import with their intensity; and the minor and transient headaches have on occasion their significance. But I am not now considering them.

It may seem rash, and of little use, for one who is not a neurologist to enter this field of inquiry. But the neurological causes of headache, though important, are few; whereas headaches are very common, both among sick folk and among great numbers who are in moderate health. Still bolder is it to write or speak of a subject which has been so well and thoroughly dealt with by observers of unusual care and discernment from ancient times down to the present. The grounds on which the following series of patients complaining of headache is discussed are: First, that, in addition to an unhurried clinical examination, opportunity was afforded of applying such scientific tests as were indicated. Secondly, the mode of life, diet and medicines were under individual care in a great number of the cases for weeks or months, so that the result of treatment could be tested in favourable circumstances. Thirdly, all the patients were observed and treated by the same group of physicians. Fourthly, an attempt is made at the numerical estimation of varieties. Fifthly, it has been possible, in a good proportion, to find out the after-history and present state.

In the ten years from January, 1925, to January, 1935, 4796 patients were admitted to Ruthin Castle. I am much indebted to Dr. Mary Watson, who read all the records and put aside those in which there was complaint of headache, in number 570. About 70 were cases of minor or infrequent headaches the notes of which give no data definite enough to be worth including in this analysis. It is to the remaining 500 cases that I propose to direct attention. The population, in the statistical sense, from which these figures were taken was composed mostly of adults from the class of business or professional men and women and their families, with a proportion of what are known as leisured folk. Many of them had been subject to the anxiety and stress, financial and other, which has been borne since the war by those in responsible positions, as well as by the whole community.

The general nature of the diseases for which these patients sought relief is shown in the following summary of an analysis of 7100 consecutive cases made some time ago by Dr. Mary Watson and Mr. A. J. Leigh, B.Sc.

> One-third of the whole—namely, 2365 cases—were the subjects of disease or disorder of the heart, arteries, and veins. One-third suffered from diseases of the throat, œsophagus, stomach, and duodenum. With diseases of the pancreas, liver, gall-bladder, appendix, colon, and rectum added, just over a half were admitted for complaints of the alimentary canal and its accessory viscera. Other large groups were in the following order: arthritis and rheumatic diseases 670 cases, nervous diseases 558 cases; next, in order of numbers, affections of the lungs, diabetes, over- or under-nutrition, affections of ductless glands, kidneys, blood, skin, excess of alcohol, tobacco and other drugs, affections of throat and nose, prostate, womb and ovaries, bladder, and eyes. Then comes a long list of diseases of all kinds of which there were less than 71 cases, that is less than 1 per cent. of each.

Classification

To the general physician there is some danger of headache being an unclassified symptom, although Galen long ago began to put headaches in order according to where he thought the pain arose. There was presumption in his classification; and if there is less in that of others as knowledge increases, there is still a good deal. Certain clinical types stand out, such as migraine, uræmia, and cerebral tumour, but many headaches do not conform to a clinical type, and often we are not sure of the real cause of the pain. To think, however, of a headache, or of any symptom, in terms, so nearly as may be, of its cause, is a help to the physician; since his aim is to remove the cause as well as to allay the symptom. I began therefore to work with a scheme based on what is known of the anatomy, pathology, or psychology of each type, compiled from plans drawn up by Liveing, Auerbach, and more recently by Wilfrid Harris, Gordon Holmes, and Pavey-Smith.

Such a classification of a large series of patients was of absorbing interest, each case being put into its place with the idea that the main cause of the headache lay here or there or was this or that. The list grew and grew until at last it dawned upon me that I was making an inventory, not only of all diseases compatible with consciousness, but also of most of the other ills that flesh is heir to. Any classification to be useful in practice must be confined to main headings. I make, therefore, no further

---

* The Croonian lectures for 1935, delivered before the Royal College of Physicians of London on May 14th, 16th, and 21st. The lectures were illustrated by numerous case-histories and lantern slides.

apology for putting forward the following clinical scheme, which really made itself as the case-histories were perused.

All headaches here discussed are regarded as intracranial, that is, by the term headache we mean a pain felt inside the head. Neuralgias and pains of nerves serving the surface of the head, such as tooth-ache, face-ache, shingles, are not included unless there was also headache.

SCHEME (500 CASES)

			Cases:
I.	Organic:	Intracranial disease	26
II.	Vascular	.. ..	50
III.	Toxic.	Nephritis, allergic, endocrine (including menopause), anæmia, alcohol, tobacco, other drugs	71
IV.	Reflex: and/or toxic.	Rheumatic (spine, muscles, and joints), diseases in head, chest, abdomen	150
V.	Functional: sometimes recognisably reflex.	Migraine, asthenia, nervous exhaustion, neurasthenia, psychasthenia, mental	203

It will be seen at once that none of these divisions has a definite boundary, each tending to pass into the next group. For example, cases of disease of the blood-vessels in the brain in group II. might be placed in group I. of organic disease in the cranium; the headache of nephritis, which is classed as toxic, may be found with, or follow upon, the headache of hyperpiesis. The functional headaches again, and especially migraine, might, many of them, as will be shown later, be put in the classes above of reflex or of allergic headaches, whilst gradations of others are found leading through the neurasthenic group to the psychotic or insane.

It is uncommon to find a person with headaches who has not more than one obvious cause, mental or physical, of ill-health, to say nothing of causes that are not recognised. The placing of any case in any group has been therefore a matter of opinion and judgment, of the value of which the lecturer is far from confident. The result of treatment is of help. If one factor is removed or its influence lessened by any measure taken, and improvement follows, the view that it was one of the causes of the headache is supported. Groups of illnesses which are poorly represented are infectious diseases and septic conditions coming mainly under the care of surgeons. Headaches due solely or chiefly to gynæcological disorders are also probably under-represented. In the whole series, counting menopausal and menstrual headaches and other gynæcological conditions, there were 69 cases occurring among 309 women, or roughly 22 per cent.

The sexes were in the proportion of three women to two men, the figures being 303 women and 197 men. The average age of the patients on admission is shown in ten-year periods on Fig. 1. It will be seen that the women were rather more liable to headaches from 20 to 40, the men later, whilst after 60 the curves run together. The average age at admission of the persons in the different groups is shown in Fig. 2. The 103 migraine patients were divided into three groups according to the age of onset—before 20 (65 persons), from 20 to 33 (20 persons), and after 40 (11 persons). In 7 the age of onset was not stated. The youngest groups on the chart are those of the psychasthenic and asthenic, and then the 20 to 33 migraine group. The cases of migraine arising before 20 were admitted a little later on the average. Then come, as the age advances, various forms of reflex and toxic headaches, leading up to the groups of nephritis and cardiovascular disease in the sixth decade of life.

Organic Headache

There were 26 cases in this group, or 5·2 per cent. of the whole. The various diseases included tumour, hæmorrhage simulating tumour, meningitis, encephalitis lethargica, disseminated sclerosis, and headache after trauma. *A chief feature of the more acute and progressive intracranial lesions is the severity of the pain.* Analysis of the cases shows the difficulty of diagnosis of tumour at an early stage and the danger of accepting a neurotic history as an explanation of present symptoms; also some recoveries after tumour, subarachnoid hæmorrhage, and cerebral syphilis.

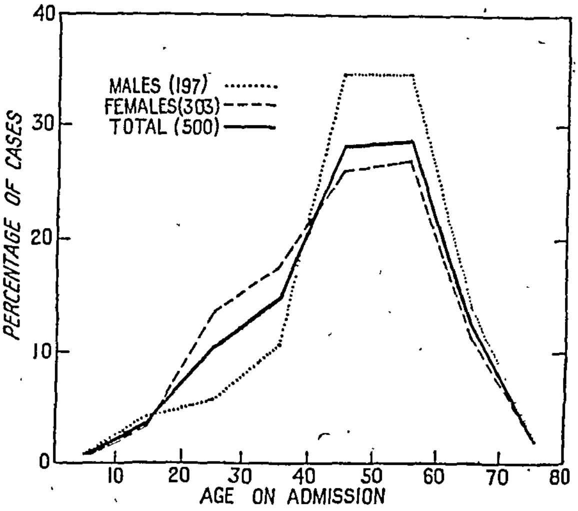

FIG. 1.—Age-distribution of patients admitted to hospital for headache.

Vascular Headache

HYPERPIESIS

In this group there were 37 persons, 24 men and 13 women. There were also 53 cases with raised blood pressure among the other groups, and especially the nephritic group, their headaches not being judged to be due solely or mainly to hyperpiesis. Thus in the whole series of 500 there were 90 cases of raised blood pressure. During the period under review of ten years 411 cases are indexed as suffering clinically from hyperpiesis. From that figure it would appear that under *one-fifth of the cases of hyperpiesis* were subject to headaches.

The site of the ache tended to be more frontal and vertical than occipital. The figures are—eyes, frontal, temporal, and vertical 20, diffuse or not mentioned 17, occipital or neck 10. Six of the female cases were at the menopause, a time of life when both headaches and a rise of blood pressure are likely to occur. Excessive use of tobacco is noted in 5 of the men, and of alcohol as well in 3. The *association of nervous strain with hyperpiesis* is close; in 15 out of the 37 patients severe nervous strain, business worry, or other anxiety was admitted.

Hyperpiesis in well-established cases has, of course, dangers that are not far away; in this series 10 of the patients had died within three years and 1 other, a severe case, seven years later. Nevertheless great and almost constant improvement in the headache and other symptoms can be obtained in this group by removal from the scene of anxieties, by regular rest and exercise, diet, venepuncture, and other measures as called for. The blood pressure falls, the headaches lessen, and some cease. Thus, of the 37 patients, 8 were examined and advised but not treated. The remaining 29 came under treatment, and benefit at the time was obtained in all, and in many of the less advanced was maintained later. This result is remarkable, and in its completeness unexpected.

An active nervous man of 47 complained of headache, giddiness, and irritability. B.P. 240/140. In seven weeks' treatment the headache disappeared and the B.P. fell to 200/116. Two years later he was readmitted complaining of tingling in hands and feet and back of head. These symptoms also disappeared and he has followed a moderately active life for three years since last admission.

A raised blood pressure was detected at the age of 46 in an overworked intellectual married woman subject to severe responsibilities and strains. An artificial menopause was induced with radium. Admitted at the age of 53 with prostrating frontal headache with photophobia, nausea, and vomiting; also, between these attacks, a duller headache with giddiness. Cardiac hypertrophy, mitral leak. B.P. 205/120. Moderate secondary anæmia. During 2½ months' treatment the pressure fell steadily and all symptoms ceased. This lady returned to her home and duties which she was able to resume, and with intermittent periods of treatment carried on for six years longer, when cerebral hæmorrhage occurred.

The striking benefit which follows rest, freedom from daily worries, and other appropriate measures cannot fail to call for the further question—How much more could the lives and the mental and physical activity of such patients be prolonged if they did not return so soon as possible to their former circumstances? Many are obliged to do so. There are, however, not a few who regard any improvement as a sign that they may plunge again into the activities and habits they enjoy, when there is no need; whereas a continuation of a quiet régime would ensure a longer and more efficient life.

OTHER VASCULAR

A group of 13 cases of cardiovascular disease contains patients most of whom would probably be in the hyperpietic class were it not for valvular or muscular disease of the heart. These were cases of serious illness. The headaches were vertical, frontal, and diffuse—none occipital. Six responded well to rest and treatment at the time.

Toxic Headache

NEPHRITIS

The main group of headaches in the toxic class, of a prognosis as grave as that of the organic intracranial group, is the class of chronic nephritis. In this group were 21 patients, 16 men and 5 women. None gave a family history of headache. In the majority the headache was persistent or frequent, but intermissions are often complete. In the same period of time 72 other patients with chronic nephritis were admitted in whom headache was not a prominent symptom. All but two of the cases were the subjects of hyperpiesis. It is therefore debatable whether the headaches are due mainly to the high pressure in the arteries or to the deficient excretion of the kidneys. Uræmic and nephritic headaches as a rule start in later life. A previous history of headaches may obscure the diagnosis. Three of these patients, for example, had been subject to migraine with aura from childhood; and in one the nephritis had been unsuspected until it was advanced to uræmia.

The site of the ache in this group was mainly frontal, temporal, or diffuse. In only one was it confined to the occiput, though four others mentioned that region. All the headaches, except a migrainous one above-mentioned, were bilateral. The causes or accompaniments of headaches prominent in other groups were conspicuously absent in this one. For example, special nervous or psychical symptoms were noted in two only of these patients. Delay in the colon was uncommon, excess of tobacco is mentioned in four and alcohol in only three, in two of whom the excess was in former years. Retinitis and uræmia were frequent and 13 of the group are known to be dead.

The cessation of headache in this group, though a great relief to the patient, does not necessarily mean that the progress of the disease is arrested. The headache may disappear as may other symptoms in severe cases when the patient comes under hospital treatment; and a man who is passing quickly into uræmia may feel and look much better for a time. The relatives, when the gravity of the case is explained, wish to take him home, and sometimes persuasion has been needed to get the patient to agree without arousing alarm in his mind.

Other cases are of intermediate severity and respond well to treatment. Under a suitable régime they may live two, three, or more years free, or nearly free, from headache and other symptoms, and with a degree of efficiency for work. In a few, better results still may follow; and, rarely, an apparently severe case may recover. Such recovery is, in my experience, associated with an infection that could be removed. In the following example, sepsis about the teeth seemed to be the cause.

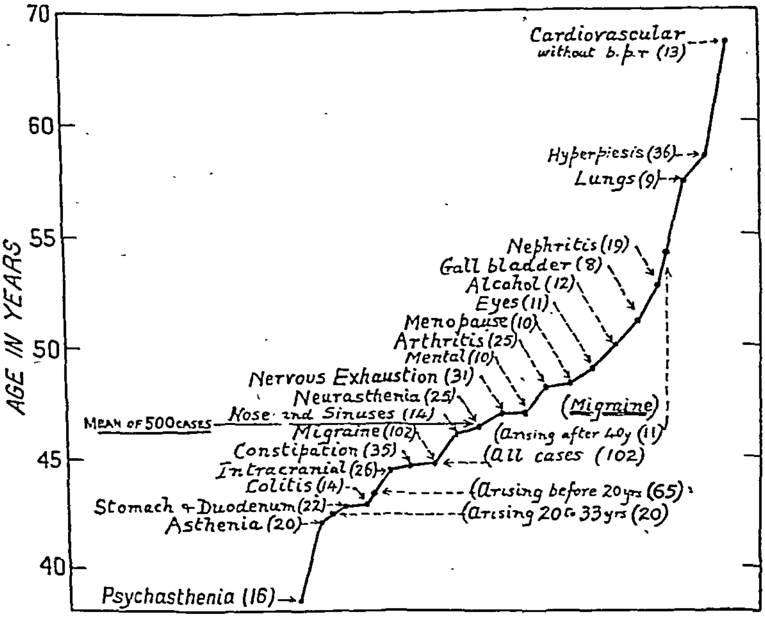

FIG. 2.—Average age of groups. The number of cases in each group is given in parentheses. Six cases of unknown age are omitted.

A man of 47, a hard worker in business and in public life, complained of a light feeling in the head which developed later into an ache. He was tired, irritable, and increasing in weight. Tobacco and alcohol were rather excessive, though not out of control. The B.P. was 210/120, the urine contained albumin and casts but gave a fair range of excretory power. In the fundi the arteries blocked the veins and there were retinitic patches and hæmorrhages. Many teeth were septic with apical abscesses. The outlook appeared grave.

The infected teeth were removed and a complete rest from work taken, with regular exercise, massage, and other treatment. In a month general improvement was manifest. The headache was almost gone and there were fewer inflammatory patches in the retina. The blood pressure had fallen to 180 and then to 150 systolic. There was less albumin in the urine, now no casts. Half a stone of weight was lost.

The patient returned home and lived very carefully for a long time, avoiding alcohol and smoking little. Later he began to take up public work again. He was seen five years after admission, looked and felt well, and was doing full work. It was difficult to recognise any abnormality in the retina.

In 34 cases of gout, 174 of diabetes, and 140 of anæmia of various kinds headache was uncommon. Among a group also of various fevers and infections headaches were frequent and variable, but called for no special comment.

HABITUAL HEADACHES

So far all the sufferers were the subjects of serious disease. Before passing on to consider the less dangerous forms of toxic headache, and the reflex and functional headaches, I will discuss briefly headaches which have become a habit. The causes of habitual headaches can be regarded as of three orders.

First, the tendency. This is often hereditary, and out of control of the doctor or patient. If, however, by any means the recurrence of headaches can be avoided or prevented it appears that the tendency may be lessened.

The second order of causes of headache includes any constant disease or abnormal state of body or mind which depresses the health. These are the conditions for which inquiry and search is made by the doctor. This is his field of work. The relief of such a disease, focus of infection or irritation, or mental anxiety may do much good. And if, as is common, or usual, there is more than one disorder, the relief of one factor only may be of much benefit.

The third order of causes of headache is that of the immediate exciting causes. The patient often, though not always, knows what is likely to bring on a headache. When he does not the doctor can help him to find out. The exciting causes, when ascertained, are, so far as may be, under the control of the patient.

The same kind of nervous or physical disorder may be either a constant or an exciting cause; examples are anxiety, overwork, eyestrain, or constipation. A study of the history, and the examination, usually lead to a definite view in this matter, which is confirmed or otherwise by the result of advice and treatment.

Nervous and Psychical Influences

The writings of those who are interested in observing any one morbid state or disturbance as a cause of headaches are often charming and convincing, whereas the laborious task of recording and reviewing a large number of cases is suited to a more humdrum and stolid mind. We have had in recent years able advocacy of various causes of migraine—e.g., of allergy, diet, endocrine dysfunction, eyestrain, and of psychical influence. All have an element of truth, but the factor to which the study of this series gives the largest volume of support is the nervous or psychical factor.

The frequency of mental stress as a constant and as an exciting cause of migraine has long been fully recognised. Such causes are, however, frequent in other forms of headache as well. In this series the records were taken impartially by different *physicians with no tendency to any point of view, or* knowledge that an analysis was going to be made. Nor was I predisposed to lay especial stress upon nervous influences. For many years, as occasion offered, I had drawn attention to the frequency with which, when a patient has been sent for observation or treatment as a neurasthenic, an investigation had shown that an undetected lesion had long been present causing the disturbing symptoms. Although most people would not rejoice to be told they had any form of organic disease, yet to one to whom nervous and psychical reasons had been offered for years to explain physical pains the relief was enormous. He had been, therefore, much interested to find that a definite nervous disturbance obvious or confessed, was recorded in the whole series in 228 out of 500 = 46 per cent. and in migraine in 51 out of 103 = 51 per cent.

The difference, therefore, is not great in this respect between migraine and other headaches.

Nervous influences, though they are mentioned in every group, are, as would be expected, less frequent in some. Such are the groups of organic intracranial disease, heart and vascular disease (though not hyperpiesis), nephritis, diseases of nose and sinuses, lungs, stomach, gall-bladder, and colon. In the groups of migraine, asthenia, nervous exhaustion, neurasthenia, the figures for recognised nervous stresses are naturally rather higher.

The subjects of nervous strain may be roughly classified as follows:—

First come the folk who are by nature unstable, the neurotic and the neurasthenic. These are upset by causes which in other people are followed by no recognisable result or reaction.

A second class includes those who have suffered undue strain from over-exertion, mental or physical. These include cases of nervous exhaustion and overtiredness. Neurasthenics are commonly told that they are suffering from nervous exhaustion. This is a pardonable kindness or compliment, and is true enough in one sense as they are exhausted easily by minor pains or strains. But in practice there can be a plain distinction between neurasthenia and genuine nervous exhaustion.

A third class contains those who are not so much overworked as anxious or worried, either about those dear to them, or business, or their own health, or other troubles.

The nervous state in the second and third groups is essentially acquired, with, in many, a degree of predisposition.

The numerical relations of these classes were as follows:—

I. Neurotic	Nervous	56	87
	Neurasthenia	31	
II. Tired ..	Nervous exhaustion	17	51
	Overtired from want of rest and various causes	34	
III. Worried	Various worries	32	90
	Anxiety about others	31	
	,, ,, business	18	
	,, ,, own health	9	

The neurotic, obviously predisposed, class made up rather more than one-third of the whole.

The late Dr. F. G. Crookshank was an eloquent exponent of the nervous or psychical influences in headaches. He wrote :—

> "The man or woman who complains of migraine or of trigeminal neuralgia is, I think, without exception, placed in some situation that gives rise to an unexpressed or unrecognised emotion of, to use Adler's words, rage and humiliation."

Taking this statement in a very general sense it appears to be true in this series of about half the cases of migraine and nearly half of the cases of headache in other groups. That headache is bound with some unhappiness is not a modern idea. Dr. Crookshank quoted from the "Anatomy of Melancholy."

> "Socrates, in Plato, would prescribe no Physick for Charmides' headache till first he had eased his troublesome mind; body and soul must be cured together, as head and eyes."

We are all bearers of the burden of disappointment and of lack of fulfilment in life or work. Some, from innate mental weakness, can carry but little, in others strength is worn down, whilst many are blessed with the power to bear and forbear.

There is a family similarity between a highly strung patient subject to migraine, or other form of headache, and other persons subject to odd days of depression, with or without alimentary disturbance. Such instability may be associated with unusual sense of atmosphere, and with vivacity and charm. People are apt not to look fairly at both sides of their own balance sheet. The assets—their gifts—they claim and rejoice in as a real part of themselves. The liabilities—limitations—they regard as outside them and ask the doctor to take them away—a very human attitude which must enlist the sympathy of each of us.

Does a placid self-contained person attain to quite the same skill or charm as he or she who is capable of depression, headaches, and despair, but can also rise to heights of skill, energy, or genius? The thought, whether justified or not, may be a comfort to all who have black hours.

If mental conflict, strain, anxiety, disappointment, or lack of fulfilment is so frequent as to be recorded in at least half of the cases of headache in this series, the question arises: How can such influences be lessened or abolished? Does the mere revelation, ventilation, and discussion of a conflict or a grievance relieve it? In some cases it is certain that it does. The novelists have never doubted. When the secret of iniquity, injustice, or suspicion is once out, there is general forgiveness or explanation; and the story soon comes to an end. In practice, however, many of the stresses revealed to the doctor, and particularly, perhaps, to a doctor who is at a distance from the patient's home, cannot be explained to those who, after the patient, are most concerned. Nevertheless, revelation still does good, a discussion may lead to advice which will help the sufferer to face difficulties and to remove them, and in many matters confession remains, now as always, good for the soul.

In the following cases, one in the group of nervous exhaustion and one of migraine, termination of a continual strain and conflict was followed by relief of headaches.

A widow of 57 with five children, with no family history ad rem, developed a periodic prostrating frontal headache which passed down to the bridge of the nose, relieved by the vomiting of mucus. There were symptoms of a non-progressive lateral sclerosis affecting both legs, especially the right, which dragged. W.R. negative. Caseous glands in the abdomen. A tentative diagnosis was that of scarring from an old intramedullary tuberculoma. There had been a great nervous strain, and the patient's circumstances were still full of daily worries from the senile irritability of a parent with whom she lived. With six weeks' treatment and encouragement there were only two less severe headaches. On returning home periodic headaches recurred. A change of circumstances with removal of the continual strain was followed by renewed health.

A woman of 28 had suffered in childhood from bilious attacks, preceded by seeing stars. She now sought admission for the relief of diffuse headaches. Omission of various foods had been tried without benefit. The home life was unhappy and unfulfilled. With later happiness and the birth of a child symptoms ceased, and five years after admission she is well.

The revelation, and in some the removal, of a recurring anxiety borne for years was followed in many other cases, as in the two quoted, with great benefit; but not in one or two. For some all strains may pass but that of memory, and who can estimate its force?

Rheumatic Headache

Passing over endocrine disturbances associated with headache at the menopause, with pituitary dysfunction, or with diabetes insipidus of pituitary type; and with mere mention of toxic headaches from alcohol, tobacco, heroin, and other drugs, I turn to a group of 26 persons, 18 women and 8 men, complaining of *headaches associated with rheumatic changes* especially in the spine and its connected muscles and fibrous tissue. In some no bony change can be detected in the joints. These are called fibrositis. In the acuter forms of lumbago and stiff neck they might be called fibromyoneuritis. In the more chronic cases there is stiffness and pain in joints, and sometimes creaking, and more or less bony change can be seen with a careful X ray examination. New formation of bone may, of course, press upon nerves emerging from the spinal column. It is surprising, however, how an advanced spondylitis may offer no painful evidence of nervous involvement, and sometimes much less restriction of movement than would be expected.

Many cases of fibrositis and arthritis of the neck and back are investigated with the hope of finding a focus of infection to which the rheumatic symptoms are secondary. In a proportion this search is successful and appropriate treatment leads to benefit. In others, and especially in arthritis of long-standing, it should be remembered, and before removing innocent parts of the body, that an original toxic process or focus may be dead and gone, leaving its damage behind it.

Most of the rheumatic headaches were intermittent, three persistent. The ache tends to be in the hinder part of the head, but it is not confined to that area. In 6 of the 26 it was entirely frontal or temporal. In one whose headaches did not begin till the age of 58, there was an aura of aphasia and spots before the eyes preceding attacks of dizziness and suboccipital headache. The association of overwork or other strain or nervousness was frequent, being noted in 14. In 10 of the 26 the diagnosis was fibrositis, no clinical or radiological evidence of arthritic changes having been recognised. Here is one such:

A man of 49 was wakened with aching in the neck and stiffness which developed into a headache and might last all day. Many of the teeth were infected and loose, and he was suffering from business and family anxieties. The cervical spine was normal to X rays.

The following is an example of a severe periodic headache, approaching the migrainous type, in a young man with fibrositis.

A man aged 32 years. Some pains around the spine began at about 15. At 21 the headaches began and, according to the patient, had been made worse by a course of vaccines. They are severe at the back of the neck and all over the head "like nerves on fire," passing into the right side of the body and thigh, and may lead to vomiting. No aura. On examination no bony changes were found. The headache is more likely to come on if he sleeps late—a migrainous feature.

The following is a case of headache with arthritis of the spine and fibrositis:—

A woman of 61 complained of an occipital headache which had been getting worse for the past 15 months. She suffered also pains in the neck, right arm, and occasionally in the leg. There was moderate colonic delay and she was overtired with the care of an epileptic child. There was spondylitis of the fifth and sixth cervical vertebræ. With six weeks' rest and treatment, including ionisation, the headaches ceased.

The following is a case of a severe periodic headache without aura, nausea, or vomiting, arising in adult life, associated with cervical spondylitis, and responding to treatment.

A woman of 41. Influenza three times in six months at 25, after which headaches began gradually. At 35 an operation for retroverted uterus, and a year later the tonsils and some teeth were removed, without benefit to the headaches, which increased in severity and frequency, occurring with intervals of ten days to a month and lasting three days. The night before a headache there was usually discomfort in the epigastrium. About 4 A.M. she would wake up with a nightmare. Pain then developed in the head and neck, with weakness of the left arm and shoulder, which were sometimes tender and stiff. There was pallor, prostration, and photophobia. Some relief was obtained by complete rest, with little food and aspirin. The patient was tired, anæmic, and moderately constipated. There was cervical spondylitis. An attack which occurred under observation was arrested by complete rest, glucose, novalgin, and the use of a suppository. After examination a régime was advised, including regular rests, massage, and diathermy to the neck muscles, and a suitable diet for the bowels, and the patient returned home. Eight months later had had three headaches only, each following overtiredness. Liable to headaches 18 months after, but they are less severe and can be more easily avoided and controlled.

Other Reflex and/or Toxic Headaches

In a small group of cases secondary to disease of the ear the site of the headache was temporal, parietal, or occipital.

EYE-STRAIN

In occasional cases of disease of the eyes, such as glaucoma and iritis, the headache was frontal and vertical. Two of the patients suffering from acute disease of the eyes, needing immediate treatment, had been subject to headaches from childhood. Such a history should not prevent as careful a search as if there had been no headache before.

Eye-strain from errors of refraction is a well-known cause of headaches; and in a great number of cases in this series the eyes had been examined and glasses used for a long time. That may be the reason why the number of patients whose headaches appeared to be mainly due to eye-strain was small. There are a dozen or so in whom no other factor appeared to be of importance; and to these must be added several in whom eye-strain was one of two or more factors. The site of the headache in this group was behind the eyes, frontal or vertical. In one only was there an ache further back, in the neck, which was accounted for by some cervical spondylitis. In that case, however, the astigmatism was the important factor as the headaches were relieved by more accurate glasses. Nervous instability or strain was prominent in this group. Reading and sewing is mentioned, or is found on inquiry, as bringing on the headache. The time of onset is more likely to be later in the day. In one only, in whom there were other factors, was there the history, so frequent in most groups, that the ache came on waking. In several cases complete relief followed the use of suitable glasses. In some in which the causes of headache were multiple, or in which the errors of refraction were difficult to adjust, with muscular weakness, relief was partial but definite.

NOSE AND SINUSES

Nasal catarrh, with or without septal abnormalities and antral disease, was mentioned in 40 cases in this group of headache patients, and in the whole number of patients 125 times. In a group of 15 the headaches were ascribed solely to these causes. Men and women were in equal numbers, as they were also in the eye-strain group. Headache from this cause may be regarded as toxæmic or as a reflex pain. It was usually intermittent; in one only persistent. The following case illustrates these points:—

A man of 28 had suffered for 18 months from pain about the right eyebrow, and a vertical headache, sometimes passing to the left. Seven months ago both turbinate bones were removed with relief. Recently the headache had returned. It was dull, worse on lying down. He was inclined to fall forward on stooping. On examination he was tender above the bridge of the nose. Diagnosis: right frontal sinusitis, confirmed by X ray.

The deceptive intermittency of a headache from sinusitis is illustrated in the following two cases:—

A woman of 65, the subject of an ulcer at the lower end of the œsophagus, complained of a stabbing headache around the right eye, which was the seat of cataract. During the three months of a successful treatment for her ulcer the headaches vanished. Later there was recurrence and, after a tiring day, the pain became severe, extending to the forehead with a fifth nerve neuralgia. Pus was found in the right maxillary antrum. After its evacuation the headaches ceased.

A young woman developed right maxillary sinusitis after influenza for which a radical operation was done. Severe headaches with resulting faintness and giddiness, made worse by reading and sewing, continued, and all the teeth were removed. Two years later she was admitted with a right fifth nerve neuralgia, following a cold, and swelling of the right cheek. This subsided. The sinuses were reviewed by a rhinologist who was unable to locate the focus he believed to be present. A severe occipital headache then developed, and at operation the right ethmoid cells were found to be infected. Complete recovery. Eighteen months later the patient states that she is free from headache and "a different person."

Cases of headache which are relieved by correction of a deflected nasal septum are reported from time to time. There was one such in this series. In another operation was advised but the patient recovered without it, from treatment for the general asthenic state.

STOMACH AND DUODENUM

In organic disease of the stomach headache was infrequent. In a period of time during which 192 cases of gastric and duodenal ulcer alone were treated, also 57 cases of growth and large numbers of other diseases or disorders of the stomach and duodenum, there were 22 cases regarded as associated definitely with a gastric or duodenal lesion, 14 women and 8 men. The headache was prominent in all and, with three or four exceptions, was bilateral. The pain was usually in the forepart of the head. In two only was it occipital, one of hour-glass stomach, and one of an ulcer in the œsophagus just above the cardia.

Cases of gastritis, liable to be complicated, as regards the possible relation to headache, with alcohol, tobacco, or other factors, all did well with treatment.

A patient with achylia and intermittent diarrhœa complained of a frontal headache which came on when he was tired or if the bowels were not open. He improved steadily with treatment, and four years later reports that headache is rare.

A direct relation of the headache to the gastric discomfort is clear in some of these cases.

Thus in a woman of 59 with gastric ulceration a right frontal headache came on with the abdominal pain, and ceased to do so after successful medical treatment.

In a case of hypotonic gastric delay the headache ceased within a month with treatment. Four years later the patient was free unless she ate unwisely.

In another young woman with gastric delay, due to obstruction from adhesions after an appendical operation, an ache over the eyes accompanied this feeling of fulness in the upper abdomen and was relieved by gastric lavage. After obstruction had been circumvented by operation the headaches and indigestion ceased and 2 st. was put on. Headache now occasionally only when overtired.

In one patient pain in the right side of the head was associated with abdominal discomfort from a duodenal pouch.

In speaking of rheumatic headaches an example was given of a severe periodic headache which developed in adult life associated with arthritis and anæmia. A similar development seemed in the case now to be related to follow gastric ulcer.

A woman of 31 had suffered about every fortnight for two years from a one-sided headache. There was abdominal discomfort and blurring of the eyes on the preceding day. In the morning the pain came on and lasted three days, ending in profuse vomiting, which was aided by drinking hot water. She was the subject of a gastric ulcer with much gastritis around it. With 11 weeks' treatment the stomach recovered. All symptoms ceased. Eighteen months later this patient is liable to a short and less severe headache at the period, but at no other time.

GALL-BLADDER

The relation of a diseased gall-bladder to headache has received attention recently. In a thoughtful paper with a review of a series of cases by T. C. Hunt it is suggested that in migraine the gall-bladder shares in the visceral stasis, such as may be observed in the stomach musculature during a severe headache, and is made more liable to yield to infection. The diseased gall-bladder is therefore regarded by him as possibly a result rather than a cause of headache. In this series the gall-bladder was known to be abnormal, or was suspected clinically, in 358 cases in the whole period under review = 7 per cent.

In the 500 cases of headache, in 17 stones were present, 8 were the subject of cholecystitis without recognised stones—i.e., 25 diagnosed cases of gall-bladder disease = 5 per cent. Disease of the gall-bladder, confirmed by cholecystography or operation, was not, therefore, more frequent in the patients with headaches than in others. There were 5 cases recorded among the 103 migrainous—the same proportion as in the headache cases in general.

The first clear case that came under my care was long before this series was observed. A man of 43 had been subject to migraine, beginning with a central scotoma, since he was 13. Attacks were recurring every few weeks. Gall-stones were present, the removal of which restored him to health. In this case we have a good example of what I have called the second order of causes of headache. The migraine had been recurring for 30 years, and it is probable that the gall-stones had been present for only a part of that time. Nevertheless, the removal of the irritation, or toxæmia, from the gall-bladder was of benefit to the migraine.

APPENDIX

That reflex or toxic headaches may occur in appendical disease is well recognised. Two examples are here given of chronic recurring headaches, one, with a history of nine years, in a boy, and the other in an elderly person.

A boy of 13 had suffered every 10 to 14 days since he was four years old from a frontal headache. One of these attacks, which was observed, began about 11 A.M. with sore feelings in the eyes. The pain soon became severe, and at 2 and 3.30 he vomited, the headache passing off about 6.30 P.M. He was frail and highly strung. The blood-sugar was normal in the attacks. X ray examination showed a bulbous appendix. After its removal he had one "sick turn." Nine years later his family doctor writes that he has had no headache since.

A woman of 60 had had appendicitis and jaundice, each twice, and separately. She complained of headache across the eyes, nausea, poor appetite. Pain in a recent feverish attack had settled in the right lower part of the abdomen, which was tender. With X rays the appendix did not fill and its site was tender; the gall-bladder gave a poor shadow with dye. Operation was advised, at which a diseased appendix was removed. The gall-bladder was healthy. Pleurisy delayed recovery. A report six years later says she lives a busy life and hardly ever has a headache.

COLITIS

Headache occurred in 16 per cent. (61 cases) of the 369 cases of colitis in the period under review. Many were complicated, but in 14 cases of various forms, including mucous, post-dysenteric, and ulcerative colitis, the headache was ascribed to the colitis, and improved with it.

CONSTIPATION

The relation of constipation to headache is universally known, the relief of headache and malaise by aperients being a commonplace of household medicine as well as the basis of considerable vested interests. Instances of temporary relief of headache by evacuation of the bowel are frequent in all groups of headaches. In habitual constipation also an aperient empties the bowel and relieves quickly an associated headache. It does nothing to cure constipation but tends to perpetuate it, replacing the natural stimulus and its resulting muscular efforts, both intestinal and somatic, by a foreign stimulus and an evacuation often abnormally loose and complete. If a regular habit can be established without irritative aperients, the recurring headaches can often be avoided.

In this series the complaint of constipation was usually confirmed or otherwise by ascertaining the rate of passage with barium, or, in a few instances, with charcoal. There are those who complain of constipation, and take aperients regularly, in whom the rate of passage is normal. These are not included.

A great many people are, of course, constipated who do not have headaches. In this series constipation was recorded in 170 out of the 500 cases. In many the headache was regarded as due mainly to other conditions. In a group of 35 it was attributed to the constipation, a conclusion which was usually justified by the result of treatment. Of this group 26 were women and 9 men. In none was there a history of headaches in early life. The site of the pain was in the fore part of the head, or diffuse—e.g., behind the eyes 10, frontal 8, temporal 4, vertical 2, &c. In 3 only was it confined to the occipital or suboccipital region. In 5 premonitory symptoms were mentioned, but none were entirely typical of a migrainous aura. Specks, stars, dizziness in the neck and on the right side, feeling ill and out of sorts and being "able to tell when a headache is coming" were among the details mentioned.

Some examples may be given :—

A woman of 58 complained of "perpetual" occipital headache, which was relieved only when the bowels were opened by aperients.

A woman of 22 complained of constipation since the age of 16. If more than four days passed without an action a headache developed with nausea and vomiting, obliging her to go to bed. With suitable treatment a regular action of the bowels was established without irritative aperients, and there were no more headaches.

The following is an example of severity both of constipation and headache :—

A young woman had always been subject to constipation which grew much worse after hysterectomy at the age of 30. Headaches then began and became severe. They occurred once or twice a month, coming on in the early morning, or at any time, above the eyes, and lasting two to three days ; relieved by lying in the dark, and aspirin. On admission at the age of 39 aspirin was losing its effect. With remedy of habitual constipation the headaches ceased, and four years later have not recurred.

It will be understood that my experience is largely with severe cases. In milder ones the treatment need not be institutional. It must be admitted, however, that patients who have been subject to habitual constipation for years are inept followers of any régime except that of purges, unless carefully controlled and encouraged.

A woman of 54 had suffered from headaches for ten years, worse the last year. They were occasional only, about every two months, but severe, confining her to bed for three days with nausea, pains in the back, and vomiting. There was much delay in the colon. Aperients were taken weekly. There was a mild secondary anæmia : 75 per cent. Hb, 3,800,000 red cells. After the period of observation a régime was suggested, and was continued by her medical adviser with a good result, confirmed by a recent report six years later.

There is, of course, a tendency for headaches to cease with advancing age ; but in many of these cases that factor can be excluded, for patients of all ages have found repeatedly that a relaxation of the routine of regular effort and suitable food has led to return of constipation and headache.

In not a few there are complications, but it is important to treat constipation always, as that treatment alone may do much good.

Thus, an active intellectual woman of 47 complained of left-sided and suboccipital headache, especially when sleep was poor. She was the subject of valvular disease of the heart, and the blood pressure was 185/100. Treatment was directed to the vascular state as well as to the bowel, in which the delay was mostly rectal. She did well in two months' treatment. Nine years later her doctor writes "the acute headaches disappeared together with the constipation."

Especially resistant are the cases in which visceroptosis and lack of muscular tone have led to the latter part of the large bowel becoming bunched up in the pelvis, sometimes adherent. In some of these, with time and perseverance, a good result may yet be attained.

Thus in a woman of 29, who had become an invalid, with constipation, backache, and a "full" diffuse headache, in two months, with physical and tonic treatment and encouragement, regular actions were obtained, accompanied by steady improvement, which has continued.

(To be concluded)

GOLD TREATMENT OF RHEUMATOID ARTHRITIS

By S. J. Hartfall, B.Sc., M.D. Leeds, M.R.C.P. Lond.

AND

Hugh G. Garland, M.D. Leeds, M.R.C.P. Lond.

HON. PHYSICIANS, LEEDS PUBLIC DISPENSARY AND HOSPITAL

THE belief in a relationship between tuberculosis and certain forms of chronic arthritis has existed on the Continent for many years, and as a result of this belief chrysotherapy has been extended to the treatment of rheumatoid arthritis with considerable success. Among others, Forestier[1] and Coste[2] in France, Umber[3] and Zimmer[4] in Germany, and Secher[5] in Denmark, have had a wide experience of gold as a remedy, and they appear to be satisfied that it is a distinct advance in the treatment of what had come to be regarded as an almost incurable malady. In this country, however, it appears to have been little used ; there is no reference to it in recent editions of standard text-books, it is not mentioned in Ray's monograph on rheumatism[6] and the report of the British Medical Association Arthritis Committee[7] only mentions its use abroad and states that reported "beneficial results have not been confirmed." The only important British papers are those of Slot and Deville[8] and of Pemberton[9] (which has been published during the preparation of this report), although Buckley[10] mentions chrysotherapy and speaks of promising results in a limited experience of its use.

Having seen some of the satisfactory results obtained in continental clinics and being impressed with the poor results usually achieved by other methods, we determined a little more than two years ago to give the new form of treatment a thorough trial. This paper is based on our experience of chrysotherapy both in private practice and with hospital cases in the arthritis clinic of the Leeds Public Dispensary and Hospital. In the selection of cases obvious secondary infective arthritis (e.g. gonococcal) and osteoarthritis have been excluded and we have accepted for treatment all other forms of subacute or chronic polyarthritis, irrespective of age and sex. The majority have shown constitutional disturbances at some stage of the illness and we have accepted this, together with an increase in the blood sedimentation rate and X ray changes in the bones of the affected hands, as supporting criteria for the diagnosis in a large number of cases. No further selection has been made nor have any foci of infection been searched for or treated, other than the most obvious sepsis requiring treatment on its own account. Auxiliary methods of treatment such as physiotherapy, electrical treatment of various kinds, and massage have not been employed, and pain-relieving drugs of the aspirin type have rarely been prescribed.

Our results concern the treatment of 100 cases and cover the period April 1933 to March 1935 inclusive. An ætiological and clinical analysis is presented together with the results of treatment.

ÆTIOLOGICAL AND CLINICAL ANALYSIS

Age and sex.—There were 16 males and 84 females. Age-distribution at the onset of the arthritis and when treatment was commenced was as follows. There was no significant difference between males and females as regards age at onset.

Age group.	At onset of arthritis.	At commencement of gold treatment.
10–19	5	0
20–29	19	8
30–39	24	20
40–49	21	28
50–59	25	27
60–69	4	16
70 or more	0	1
Unknown	2	0

The *duration* of the arthritis was very varied and ranged from one month to 37 years. There were 17 cases in which the arthritis had existed less than one year, 21 from one to two years, 22 from three to five years, 19 from six to ten years, 15 from eleven to twenty years.

There was a *family history* of rheumatoid arthritis in blood relations in 20 cases and a history of rheumatic fever in 6. In 5 cases the patient had been suspected of pulmonary tuberculosis in the past, in 17 cases there was a history of tuberculosis in a blood relation, and in a further 5 there had been close contact with pulmonary tuberculosis. Thus, for what it is worth, there is an association with tuberculosis in 27 cases.

Physical type.—We did not find any predominance of a particular physical type. The cases were equally divided among individuals of slight, medium, and heavy build, but with regard to colouring 80 were dark or medium and 20 fair.

Type of onset.—The onset of the arthritis was acute in 65 cases and chronic in 35. In 64 there was considerable constitutional disturbance with marked loss of weight, debility, slight anæmia, &c. at the onset, while similar disturbances developed at a later date in another 9. In the remaining 27 there were no constitutional disturbances.

The joints most commonly affected at the onset were the small joints of the hands and feet—namely, in 39 cases (hands 24, feet 15). The next most common sites of onset were the knees 18, shoulders 11, ankles 9, spine 6, hips 4, elbows and wrists 3 of each. In 8 cases multiple joints were affected at the onset and in a further 5 the onset was generalised.

Progress.—The disease had usually spread to involve more than one joint. It had pursued a variable course, with exacerbations and remissions, in 20 cases. In 10 there had been rapid progression and 70 were getting gradually worse.

Previous treatment.—In order to show the effectiveness of gold, we have recorded the previous treatment (other than drugs) and the benefit obtained. The number of patients who had previously had one or more forms of treatment was 62. Of these 34 had had spa treatment, some on several occasions and usually at Harrogate, but only 5 of these claimed any lasting improvement. Diathermy or radiant heat had been given in 29 cases, and vaccines in 25. Nine of these 25 had had Warren Crowe's vaccine and 2 only claimed some relief; the remaining 16 had stock or autogenous vaccines of various kinds, 3 of whom thought that these had helped. Courses of massage had been given in 18 cases. In a further 17 focal sepsis had been treated, but in only one was any improvement claimed. Protein shock therapy had been used in 4 others with little effect, and 3 had been subjected to orthopædic procedures.

The *joints affected* at the time treatment was commenced were the fingers 94, knees 89, ankles 84, wrists 82, shoulders 82, feet 68, elbows 65, cervical spine 51, hips 45, lumbar spine 45, temporomaxillary 41, sternoclavicular 37, dorsal spine 33. For the sake of brevity no attempt is made further to subdivide the particular joints affected in the hands and feet.

Associated disturbances.—In 85 cases the pulse-rate was above the normal; in 33 it was between 80 and 90, in 12 between 90 and 100, and in 40, 100 or more. The blood sedimentation-rate was estimated before treatment in 78 cases, the Westergren method being employed. We have allowed a sedimentation-rate of up to 9 in the first hour as being normal. The rate was increased in 67 cases (86 per cent.). The actual increase in sedimentation-rate was 10 to 19 in 22, 20 to 29 in 14, 30 to 39 in 13, and over 40 in 18. We found 7 cases with anæmia, 13 cases had a markedly raised blood pressure, and 4 of these had slight albuminuria. Three patients had psoriasis, 1 diabetes, 1 a curious dystrophy of the nails, and 1 chronic chorea.

X ray appearances.—The hands were radiographed in the majority of cases but we do not intend to present any analysis of the radiological findings in view of the recognised difficulties in their interpretation.

METHOD OF TREATMENT

We have favoured the intravenous method of administering the gold salts using gold sodium thiosulphate, usually in the form of Crisalbine. Occasionally the intramuscular preparations Myocrisin and Solganol B. Oleosum have been employed, the use of these being limited to those patients in whom the superficial veins were small and the injections difficult.

During the two-year period we have given 1147 injections of gold salts, and of these 1027 were intravenous and 120 intramuscular; of the intramuscular injections 57 were solganol and 63 myocrisin. The total weight of gold salts thus administered was 198 grammes, given in 150 courses. The largest quantity of gold given to any one patient was 13·9 g. of gold sodium thiosulphate in 41 injections, comprising 4 courses spread over a period of two years. So far as gold sodium thiosulphate is concerned we adopted the following scheme of administration; 0·05 g., 0·1 g., 0·2 g., and thereafter 0·2 g. at weekly intervals until a total of not more than 2 g. had been given. This procedure, however, was widely varied from patient to patient, according to the particular reactions and the response. Depending on the progress of the case two, three or more courses were given, with an interval of at least six weeks between courses.

REACTIONS

Painful exacerbations in the joints occurred in 47 cases, and in 45 of these the pain was felt after one or other of the first six injections, but not later. Two cases had delayed pain reactions, both after intramuscular injections. The pain was usually noticed in the joints within 48 hours of the injection and lasted two or three days; quite frequently the pain was most severe the fourth day after the injection. We have come to regard such pain as a very good prognostic sign, and although our figures are not yet complete in this respect we can say that over 80 per cent. of patients who had such painful reactions went on to marked improvement or apparent cure.

The toxic reactions following the administration of gold have received wide publicity both in the lay and medical press. For this reason we have carefully recorded all the toxic manifestations encountered with regard to character, frequency, severity, and time-incidence. Toxic reactions have been observed in 45 of our cases in the following approximate order of frequency. The commonest reaction was a generalised pruritus which occurred in 36; of these 28 developed erythema and in 4 this went on to desquamation, in 1 case severe and generalised. Diarrhœa developed in 10 cases and 3 of these had abdominal colic. Soreness of the mouth was complained of in 9 cases and 3 of these went on to ulceration and complained in addition of a persistent unpleasant taste, while 2 others complained of dryness of the mouth. In 4 cases vomiting occurred within a few hours of the injection and 1 patient had immediate nausea without vomiting.

The urine was tested in every case at the beginning of treatment, in many cases before each injection, and in all cases showing toxic reactions. Albuminuria accompanied other toxic reactions in 12 per cent. of cases and occurred once as the only toxic reaction.

We have seen isolated examples of hyperkeratosis of the soles, pustular dermatitis of hands and feet, labial œdema, herpes zoster, erythema nodosum, lichen planus and purpura, all of which have been observed by others.[11] [12] We have not encountered any toxic manifestations in the central nervous system.[13] We have been impressed by the fact that all these reactions were not delayed but developed within a week of the last intravenous injection.

We have not been helped by the use of sodium thiosulphate, either by mouth or intravenously, in the prevention or amelioration of toxic symptoms; we have formed the impression that it is of little or no therapeutic value, and in the treatment of toxic disturbances we have relied entirely upon symptomatic measures.

Three of our patients have died.

The first was a woman, aged 32, who defaulted, having received 8 injections of crisalbine (total 1·0 g.), with much improvement of her arthritis; three months after her last injection she developed a sore-throat and she was admitted to St. James's Hospital when her total leucocytes had fallen to 2000 per c.mm. with agranulocytosis. She died after ten days and an autopsy was carried out by Dr. C. J. Polson who found the characteristic changes in the fauces and bone-marrow of agranulocytic angina. There was no evidence that this patient had taken amidopyrin. It is doubtful whether gold salts were the cause of this blood dyscrasia, for we have not seen delayed toxic symptoms after *intravenous* injection. At the same time we realise that gold has been held responsible for agranulocytosis. Toxic symptoms are, of course, delayed after *intramuscular* injection (e.g., Holmes[14]).

The second was a woman, aged 45, who had been crippled with arthritis for thirteen years. She had been treated with Warren Crowe's vaccine on and off for ten years without improvement. The preliminary tests as to suitability for gold treatment showed no contra-indications. She received two injections of crisalbine, each of 0·05 g., after which she immediately developed an itching erythema which went on to generalised scaling, a condition which lasted a month. The arthritis improved but no further gold was given as the immediate reaction after small doses suggested an idiosyncrasy and was unlike the toxic reactions with which we were familiar. Five months later, despite the knowledge of this severe upset, the patient was so impressed by the improvement seen in other patients that she persuaded us to recommence gold treatment. She was given a preliminary injection of 0·01 g. crisalbine, one-fifth of the usual initial dose, followed by a further four doses, making a total of 0·36 g. After the fifth injection she developed a fine petechial rash, and a week later there was a sparse purpura on the face and limbs; during this week there had been recurrent epistaxis and vaginal hæmorrhage. The blood count was now: red cells, 2,920,000; hæmoglobin, 40 per cent.; colour-index, 0·7; leucocytes, 8400 (85 per cent. polymorphs). Immediate admission to hospital was advised but for personal reasons this was refused. Ten days later she had a severe hæmatemesis, and the next day she was admitted to hospital moribund; she died before blood transfusion could be carried out. The blood count on admission, an hour before death, was: red cells, 2,540,000; hæmoglobin, 40 per cent.; colour-index, 0·8; leucocytes, 8700; the platelets had fallen to approximately 38,000.

A partial autopsy revealed multiple acute hæmorrhagic erosions of the gastric mucous membrane and there was altered blood in the intestine. Most of the viscera showed petechial hæmorrhages. The spleen was enlarged, the malpighian bodies standing out with a remarkable degree of pallor against the congested pulp. The left renal pelvis showed a large area of hæmorrhage extending into the calyces. The bone-marrow appeared normal in the clavicles, sternum, and ribs. There were multiple small hæmorrhagic infarctions in the lungs and considerable pulmonary œdema. The brain was not examined.

The third case was that of a woman, aged 63, who had suffered from arthritis for five years. The preliminary investigations showed a normal urine, blood-urea, and blood pressure; the sedimentation-rate was 34/58 and the pulse 98. She was given 4 weekly injections of crisalbine (total 0·85 g.), after which she was given myocrysin (intramuscular) owing to injection difficulties; she had five injections (total 0·95 g.) which were followed by itching erythema; after an interval of two months she had 4 more injections (total 0·6 g.) followed by a similar rash; after a further two months she was given 5 more injections (total 0·75 g.), making a total of 2·3 g. of myocrysin. The treatment covered a period of one year and was followed by "wonderful improvement." Seven weeks after the last injection she developed hæmaturia and later hæmatemesis, for which she was admitted to St. James's Hospital; a few petechial hæmorrhages were noticed on admission. Hæmaturia continued and the patient died after three weeks. An autopsy was again carried out by Dr. Polson who found subdural and sub-endocardial hæmorrhages, with blood in the stomach, intestines, renal pelvis, and bladder. Death was clearly due to purpuric hæmorrhage.

In reviewing these three deaths it is of interest that all have resulted from blood changes. We have no doubt that death in the second and third cases was directly due to the effects of gold, both patients dying of purpura. Compared with our other cases the second death followed very small doses and the third case had only received an average amount of gold; both women had previously shown cutaneous sensitivity of the common type. It is unfortunate that these cases did not come under our care during the terminal illness, and in no case was specific treatment instituted, such as pentose nucleotide in the first case or blood transfusion in the other two.

RESULTS

It is difficult to give a satisfactory classification of the results of treatment in chronic arthritis. A number of our patients were almost bed-ridden, incapable of dressing, washing, or feeding themselves and unable to walk; many had been in this condition for years, despite innumerable forms of treatment. Most of these cases have shown a remarkable improvement, often approaching a return to normal; but so long as there was any joint pain we continued treatment and such cases have been classified "marked improvement." For example, the patient who received the largest quantity of gold (13·9 g.) had been for four years unable to wash or feed herself and could only hobble a few yards on two crutches when treatment was commenced two years ago. At the present time she has no disability in her upper limbs, walks freely and unaided, and only complains of pain and stiffness in the right ankle; for this reason she is classified "marked improvement" and not "cure." It is interesting that this patient has become pregnant for the first time for fourteen years. We are convinced that no case is too far advanced to expect some improvement from chrysotherapy, though of course complete cure is more likely in early cases. Gold has no effect on ankylosis or subluxation.

Ten patients have been discharged as apparently cured—that is, with complete freedom from pain and disability other than that due to bony ankylosis. Most of them were severely crippled before treatment was commenced. Fifty-six cases are classified as "marked improvement"; this often gives but a poor impression of the degree of recovery, but all these patients still have some pain or disability and most of them are still being treated. Twenty-two have shown "slight improvement"; of these only two have completed one full course of treatment. Five, none of whom have completed a course of treatment, show no improvement in their arthritis. The remaining 4 patients defaulted at the beginning of treatment.

	Cases and per cent.
Apparent cure	10 (10·4)
Marked improvement	56 (58·7)
Slight ,,	22 (23)
No ,,	5 (5·2)
Died	3 (3·1)

In addition to the improvement in the arthritis there is usually a striking improvement in general health. Of 69 patients with significant upset of general health 51 showed marked improvement, 16 slight improvement, and 2 no improvement; none of the last two groups have completed a full course of treatment. In every case there has been improvement either in arthritis or in general health. There is usually a marked fall in the pulse-rate and blood sedimentation-rate after treatment. In the case of the diabetic patient her arthritis, which had been progressive despite all previous treatment, made a striking recovery and she was able to reduce her insulin from 28 to 6 units daily.

DISCUSSION

Gold has been used in the treatment of pulmonary tuberculosis since 1916 and the wide variability of tolerance of the individual has always been appreciated. There can be no doubt that at present we have no practical means of determining the optimum dose for the individual. In the case of tuberculosis we may cite Shaw,[15] who in 1930 referred to the previous "heroic dosage" employed and then proceeds to recommend three weekly doses of 1·0 g. of gold sodium thiosulphate, the total course consisting of 4·6 g. On the other hand the dermatologists have used minute doses of gold in the treatment of lupus erythematosus and have also occasionally noted toxic reactions.[11] Our own dosage has usually been midway between these extremes, and at the present time we are investigating the effects of still smaller doses.

Despite the frequency and occasional severity of the toxic reactions we have continued to use chrysotherapy. These unfortunate effects can in no way alter the fact that many patients have made a remarkable recovery. There can be no doubt that chrysotherapy is a most important advance in the treatment of what was so frequently an incurable disease, and like most other advances in therapeutics the experimental stages are being attended by occasional catastrophes. Despite these drawbacks we feel that gold gives more favourable results than any other single form of treatment and that it is curative and not merely palliative.

CONCLUSIONS

1. Chrysotherapy in relation to rheumatoid arthritis is still in the experimental stages, but we believe it to be the most important form of treatment. We have treated 100 cases over a period of two years with excellent results in 70 per cent. and some improvement in 90 per cent. of cases; these included many long-standing cases with gross disability.

2. Owing to the marked variation in susceptibility no rules as to dosage can be laid down and treatment must be individualised. In some cases treatment must be prolonged for two years or more. Probably the doses employed are still too large and it is possible that the interval between courses should be not less than three months.

3. Toxic reactions have occurred in half our cases. These are usually mild and do not contra-indicate further treatment. Hæmorrhagic reactions and exfoliative dermatitis, however, may be fatal and no more gold should be given to patients who develop them. Other than gross renal or hepatic disease, we have found no absolute contra-indication to chrysotherapy before the onset of these serious reactions.

4. Chrysotherapy should only be undertaken by those who are fully alive to its dangers. The patient should be warned of these possibilities. The urine should be tested before each injection. Especial care must be taken after the occurrence of toxic reactions. It is essential that every patient should be seen every week during, and for three months after, each course of treatment.

We wish to express our thanks to the almoners department of the Leeds Public Dispensary and Hospital for enabling us to keep close contact with out-patients.

GOLD TREATMENT OF TUBERCULOSIS

A STATISTICAL STUDY

BY B. A. PETERS, M.D. Camb., D.P.H.
MEDICAL SUPERINTENDENT, HAM GREEN HOSPITAL AND SANATORIUM, BRISTOL; LECTURER IN INFECTIOUS DISEASES IN THE UNIVERSITY OF BRISTOL; AND

C. SHORT, M.B. Edin., D.P.H.
ASSISTANT MEDICAL OFFICER, HAM GREEN HOSPITAL AND SANATORIUM

IN attempting to assess the value of any form of therapy for pulmonary tuberculosis in sanatoria peculiar difficulties are encountered. The results of treatment differ in every case, according to the previous duration of illness, the age of the patient and the type of disease. The method of using a new treatment for alternate cases is not applicable, since some of the cases would be moribund and others so slight that rapid improvement might be expected with ordinary treatment. If any method of selection is used an imponderable error is introduced.

To eliminate the age factor we have put together the results of treatment in one age-group only, 16–26, during the past five years. This group contains the highest proportion of cases considered most suitable for chrysotherapy by all observers. Over the whole period one-third of the cases, and during the last three years, one-half have had gold in the form of Crysalbine, Allochrysine or Myocrysine in the usual weekly doses of 0·1–0·5 g. for six to eight weeks, followed in many by a repeat course after an interval of six weeks. During the past three years those not treated with gold have been slight cases or cases with pleural effusion in whom the prognosis was very favourable without special treatment, or moribund cases. Taking the whole group into consideration, whether they have received gold treatment or not, an improvement in the results of a five years' working should be evident if gold were of any value, compared with a similar control group in the previous five years, other factors being equal. The number of cases treated by artificial pneumothorax are approximately equal in both groups. Dr. C. J. C. Faill, the tuberculosis officer who is responsible for allocating cases to our institution, informs us that the cases sent to us have been chosen on the same basis during the whole ten years—another institution receiving the majority of the earlier cases.

TABLE I.—*Pulmonary Tuberculosis in Bristol* (Age-group 15–25)

Year.	Notifications.	Deaths.	Percentage of deaths to notifications.
1925	195	121	62
1926	186	133	68
1927	175	143	81
1928	177	123	69
1929	153	90	58
1930	159	89	55
1931	161	86	53
1932	129	53	41
1933	163	78	48
1934	132	54	41

Where the test and control series are not contemporary one has to consider the trend of mortality of the disease in the area from which the cases are drawn. Prof. R. H. Parry has kindly provided us with the figures of notifications and deaths in an almost identical age-group, 15–25, in Bristol during this ten years (Table I.). From these it is evident that while the number of notifications is diminishing, the percentage of deaths to notifications is decreasing more rapidly, which suggests that the disease is becoming less fatal in this age-group in Bristol. This factor should show itself in our figures in an improvement in the results.

TABLE II.—*Control Group* (1925–29) *Before Use of Gold* (Age-group 16–26)

—	Died.	Worse.	Non-quiescent (improved).	Quiescent.	Total.
1925–29 ..	104	62	177	147	490
Percentages	21·224	12·653	36·122	30	—

On comparing the test and control groups (Tables II. and III.) it will be observed that the differences in the results of treatment in the two series are statistically negligible whether based on the whole five years during which one-third of the cases received gold or in the last three years when one-half of the cases had gold. One can only conclude that gold treatment is of no appreciable value.

TABLE III.—*Test Group Treated with Gold* (1930–34) (Age-group 16–26)

The examination of our statistical results has been a painful shock, for we were convinced whilst carrying out this costly method of treatment that in chrysotherapy we had found a valuable aid; many of the cases seemed to do extremely well. But one tends to forget that many cases previously did extremely well even without gold. It is to us a sad reminder of the extreme fallibility of clinical judgment when exposed to the cruel light of a controlled statistical inquiry on a large number of cases.

POST-OPERATIVE INTRACRANIAL THROMBOSIS IN CHILDHOOD

BY P. R. EVANS, B.Sc., M.B. Manch., M.R.C.P. Lond.
LATE HOUSE PHYSICIAN, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET, LONDON

INTRACRANIAL thrombosis may occur in children, as in adults, after local operations for conditions such as mastoiditis; but intracranial complications following two operations so different as herniotomy and the extraction of teeth stimulates search for other cases.

Schwenninger[1] in 1910 stated that classical thrombophlebitis after operation was never seen before puberty—unlike septicæmic thrombophlebitis, which attacks infants. Schnietzler[2] agreed with him. Schwenninger's statement, however, was too sweeping, though he brought out the useful distinction between septicæmic and non-septicæmic cases. Case 5, of the series here described, exhibits a classical, but not a fatal, pulmonary embolism. The records of about 11,500 post-mortem examinations made at the Hospital for Sick Children, Great Ormond-street, between 1860 and 1934, contain only one other case of post-operative pulmonary embolism, but there were two septicæmic intracranial thromboses, both following operations for cleft palate. There were also three cases of intracranial thrombosis after "clean" operations, two of them herniotomies, the other Loreta's operation for pyloric stenosis. In two further cases there was infection at the site of operation, but septicæmia was not demonstrated. In another there was septicæmia, but it was probably due to septic thrombosis. All occurred in this century, the age of major surgery. The superior longitudinal sinus was most commonly affected (5 out of 8 cases).

Little attention has been paid to this complication of pædiatric surgery: Byers and Hass[3] mention three cases but give no details; Wyllie[4] recognises the occurrence, and there is a good short account in Garrod, Batten, Thursfield, and Paterson's text-book,[5] in which three of the cases described here are instanced.

SEPTICÆMIC CASES

The first type then is the septicæmic, illustrated by the following:—

CASE 1.—A girl, aged 2 years, was admitted to the Hospital for Sick Children under Mr. Collier on March 2nd, 1910, for repair of a cleft palate which had been operated on eighteen months before. On March 4th a flap operation was performed. In the evening the patient vomited and collapsed. Two days later the temperature was 104°, tremor of the arms and legs was noted, the knee-jerks were present, ankle-clonus could be elicited, there was paralysis of the right internal rectus muscle. Next day the child was drowsy, temperature remained high, and she died on the 9th.

Post mortem, the superior longitudinal sinus was found to contain pale clot, and the parietal and temporal cortex was congested and œdematous. There were petechial hæmorrhages under the pleura of the collapsed lower lobe of the left lung; the endocardium was stained a brick red; the liver was large and fatty; the spleen large and semi-diffluent. Post-mortem culture of the heart's blood produced streptococci.

This demonstrates the fairly early affection of the motor areas, which Byers and Hass found usual, due to interference with their venous drainage by clotting in the superior longitudinal sinus. Case 4 also shows this.

CASE 2.—A boy, aged 3 years and 7 months, was admitted to hospital under Mr. Barrington-Ward on Jan. 23rd, 1931, for repair of a cleft palate which had been operated on three months before. On Jan. 28th it was resutured, but by Feb. 3rd it had again broken down. Three days later the temperature was high, there were signs of pharyngitis and bronchitis. Subsequently the temperature swung between 102° and 104°. On the 17th blood culture produced a pure growth of hæmolytic streptococci and death occurred a few hours later. The autopsy disclosed ante-mortem clotting at each end of the superior longitudinal sinus, and in some of the veins leading to it. There was no staining of the endocardium, the liver and kidneys were very pale, the spleen large and diffluent.

Symptoms of the thrombosis were in this case masked by the general infection. Thrombosis was not due to local infection from the palate, for the superior longitudinal sinus only was affected, and it seems probable that it was secondary to the septicæmia.

In the next case to be described there was also a wound infection (streptococcal). The state of the liver and the spleen, the absence of any recorded neurological signs, and the desperate illness of the child, indicate that intense toxæmia or septicæmia was the important factor.

CASE 3.—A boy, aged 2 years and 7 months, was admitted on Oct. 26th, 1909, with megacolon. On the 29th Sir Arbuthnot Lane removed one foot of the sigmoid colon, and the child did well until Nov. 3rd, when the pulse became quick in the afternoon, and in the evening the patient suddenly collapsed and became cyanosed. The lower part of the wound was opened, turbid serum escaped, from which streptococci were cultured. He became weaker and died on Nov. 5th. His temperature was never raised above 101°.

Post mortem the operation wound appeared healthy. The superior longitudinal sinus and its tributary veins were thrombosed, but the other sinuses were not affected. The brain substance around the affected vessels was soft and deeply congested. The middle ears were dry. There was consolidation of the posterior portions of the lower lobes of both lungs. There was no free fluid in the abdomen, the bowel anastomosis was covered with lymph and appeared healthy. The large intestine was enormously dilated, the small normal. There were fatty changes in the liver, and the spleen was enlarged and friable.

CASES WITHOUT SEPTICÆMIA

Of the next four cases, which were non-septicæmic, two followed herniotomy (as also did the isolated case of fatal pulmonary embolism, which is not described here). It is difficult to believe that this is merely accidental; it is indeed what might be expected. The great rarity of classical thrombophlebitis following operation in children must be partly due to the fact that the operations performed on them differ from those performed on adults. It most frequently occurs after myomectomy, hysterectomy for uterine cancer (Chauvin[6]), and prostatectomy (Wilson[7]). The child is, at present, immune from surgical assault on uterus and prostate. But Chauvin's figures show that there is one other operation after which venous complications are at all common—this is herniotomy—an operation often performed in youth.

CASE 4.—A boy, aged 4 years, was admitted to hospital on Feb. 9th, 1911, under Mr. Corner, for radical cure of bilateral inguinal hernia, which was performed on the 10th. Next day the child "became more or less mad"; he shouted frequently, his eyes were fixed and staring. On the day after that he was convulsed, especially on the right side. He had another fit, this time bilateral, on Feb. 13th; his temperature rose to 107° F., and he died early on the morning of the 14th.

At autopsy a small firm thrombus was found towards the anterior end of the superior longitudinal sinus; there was a small extravasation of blood over the front of the left parietal lobe; many of the capillaries in the Rolandic areas were thrombosed. There was a little muco-pus in both middle ears. All lobes of the lungs contained patches of consolidation. The peritoneum in the right internal inguinal opening showed some congestion; the wound was healthy.

CASE 5.—A girl, aged 3 years and 3 months, was admitted to hospital on May 18th, 1934, under Mr. Higgins, for cure of a left inguinal hernia. She was almost blind, having congenital dislocation of both lenses. On May 28th radical cure was performed. On the following day she had sudden dyspnœa and cyanosis, with a weak pulse. Three days after operation she developed a left hemiplegia, with a left facial paralysis; the left plantar reflex was extensor. The cerebro-spinal fluid was normal, the blood-urea 26 mg. per 100 c.cm. On the 9th day her condition was still poor; she was transferred to a medical ward under Dr. Cockayne.

At this time she resented examination; her pupils reacted inconstantly to light but were equal; iridodonesis was present in both eyes. The discs were not seen owing to the abnormal position of the lenses. Both abdominal reflexes were absent, both knee- and both ankle-jerks present, the left plantar reflex extensor, the right flexor. There was difficulty in looking to the right with both eyes, slight weakness of the muscles supplied by the 5th and 7th cranial nerves on the left side, and complete paralysis of the left arm and leg. The operation wound was healthy.

On the 18th day there was some recovery of power, and the girl could speak a little ("Mummy make it better," &c.). But on the following morning she could not be waked. She was in fairly deep coma, but opening the mouth was strongly resisted; flexion of the left knee occurred spontaneously during examination. The pupils were fixed, the right being dilated, the left contracted; there was a divergent squint; face normal, eyes shut; left arm and leg as before; right arm and leg paralysed and limp. Respiration was slow and regular; pulse-rate 140. Both corneal reflexes were present, the left being more active than the right. Abdominal reflexes could not be obtained, both plantars were extensor, knee- and ankle-jerks were absent. The cerebro-spinal fluid was normal.

In the evening the pulse-rate was 60, the patient vomited, and convulsions limited to the left arm and leg occurred. There was a similar attack the next day; early in the morning of the 21st day after operation she died.

At post-mortem examination a dark red consolidated area was seen at the base of the lower lobe of the left lung; on section firm clot projected from smaller and larger vessels, and the consolidation was seen to extend 3–4 cm. into the lung. On microscopical examination all the larger vessels were seen to contain adherent thrombi. There was no appearance of infection. Firm clot was also present in the basilar artery and the circle of Willis, in the left internal jugular vein, and the lateral sinus. There was very extensive softening of the whole of the right cerebral hemisphere, the thalamus and base being more affected than the parietal and occipital cortex; there were numerous pin-point hæmorrhages throughout. An old subarachnoid hæmorrhage involved the right temporoparietal region. The left hemisphere showed no necrosis or hæmorrhage. The hernia wound was clean; the inguinal vessels contained no thrombus (3 hours after death). The liver was engorged, with paler areas of fatty change, the other organs normal.

This child had sufficiently clear-cut signs to permit a tolerably accurate diagnosis (during life) of pulmonary embolism, followed two days later by embolism or thrombosis on the right side of the brain, and two weeks later by similar affection of the left side. The absence of convulsions until two days before death is interesting but not surprising, for the superior longitudinal sinus was not involved.

CASE 6.—A boy, aged 9 weeks, was admitted to hospital in a very wasted condition on August 26th, 1908, under Dr. Colman, with symptoms of pyloric stenosis for the previous six weeks. On August 28th Mr. Waugh incised the stomach and dilated the pyloric canal with Hegar's dilators. A little diarrhœa and vomiting followed the operation, but had ceased by Sept. 3rd. On Sept. 11th marked head retraction was noticed; blood-stained, sterile, cerebro-spinal fluid was withdrawn by lumbar puncture. Death occurred next day.

Post mortem the superior longitudinal sinus was found to contain firm, slightly adherent clot; the contributory veins were thrombosed. On the surface of the brain was effused blood, on the left side the corpus striatum, and the internal capsule were softened and contained small areas of hæmorrhage. There was muco-pus in both ears; the tympanic membranes were normal. The pylorus was much hypertrophied, the incision into the stomach had healed, there was a little plastic peritonitis, the adhesions being easily broken down, the other organs normal.

This case has been previously mentioned by Sheldon.[8] He considers it as one of the marantic class, but it is difficult to understand why thrombosis should have occurred about a week (probably) after a successful operation for the relief of the condition.

CASE 7.—A. S., aged 1 month, was admitted to hospital under Sir Arbuthnot Lane, on April 15th, 1909. He was a well-nourished boy with a double hare-lip and cleft palate. An operation was performed on the 16th, but by the 22nd the flap had almost completely broken down. On the 25th he was very ill; on May 3rd he died.

The post-mortem examination revealed a small cerebral hæmorrhage at the posterior part of the upper frontal convolution on the right side; the superficial veins in the immediate vicinity showed thrombosis. There was pus in the right middle ear. There was clear fluid in the serous cavities, œdema of both lungs and consolidation in the upper part of the right lower lobe; the liver was firm, the spleen not enlarged, the other organs normal.

Thrombosis in this case was very limited, and its position does not suggest spread from the infected wound. There was no evidence of septicæmia, as there was in the other palate cases, but it is not immediately obvious what killed this child.

It is difficult to know why these non-septic thromboses occur. In Case 5 intracranial clotting was probably due to embolism. No cause appears in cases 4, 6, and 7. In Case 4 death took place soon after the operation, and a falling blood pressure with surgical shock may have caused complete stasis in the rigid sinuses, which cannot contract to compensate for a small flow of blood. But something more than stasis is needed to produce intra-vitam clotting.

Intravenous therapy has been suggested as a cause, but there is no record of anything being given to any of the uninfected cases by the intravenous route. Trendelenburg's position has also been accused, but it is unlikely to have been used in these cases.

AN UNCLASSIFIED CASE

CASE 8.—A girl, aged 3 years and 8 months, was admitted to hospital on Dec. 4th, 1934, under Dr. Pearson. Two weeks previously the first and second left *lower* molar teeth had been extracted, under ethyl chloride and ether anæsthesia. Since then she had had a cold in the head. Four days before admission she had a frontal headache, without pyrexia.

On admission she had a temperature of 102°, and was delirious. There was œdema of both eyelids, more marked on the left, slight œdema of the forehead, and blueness of the middle of the forehead, the lower eyelids, the nose and the philtrum. The median frontal vein was firm and thickened. There was bilateral proptosis. The Vth left cranial nerve was paralysed, the right nerve was less affected. Kernig's sign was positive, and there was some neck rigidity, but no other neurological abnormality, except haziness of the nasal side of the left optic disc. The tongue was dirty and dry, the sockets of the first and second left lower molars contained yellow exudate. A few teeth were carious, the tonsils were not enlarged, but there was a post-nasal discharge and blood and pus were seen in the left nostril. There was no tenderness over the frontal and maxillary air sinuses, and no definite abnormality was seen in an antero-posterior radiogram of the skull. On Dec. 5th there were 25,000 white cells per c.mm. of blood; 92 per cent. were polymorphonuclear. The cerebrospinal fluid was turbid and blood-stained, and contained albumin 0·4 per cent., chlorides 0·68 per cent., no sugar, and 560 cells per c.mm., of which 94 per cent. were polymorphonuclear; no tubercle bacilli were seen, and the fluid was sterile on culture. Blood culture gave a growth of *Staphylococcus aureus* in two days. The temperature continued to vary between 101° and 104°, and the child died on Dec. 15th.

Post mortem the thrombosed middle and left frontal veins were prominent, and small thrombosed veins were visible over the bridge of the nose and external to the left eye. There was bilateral proptosis, and there were many small abscesses in the left eyelid.

The nose was examined from above, no septic focus was seen in it, or in the mastoids, the middle ears, or the jaws. The body of the sphenoid bone was largely eroded, and contained a drachm of thick pus. Both cavernous and both intercavernous sinuses were distended by septic thrombus breaking down into greenish-white pus. Pus extended into the left orbit, and the ophthalmic veins on both sides were thrombosed. The superior longitudinal sinus contained post mortem clot; the other venous sinuses, and the internal jugular vein, the vein of Galen, and the superficial vessels of the cortex contained fluid blood. The base of the brain was covered with thick adherent pus, yellow lymph, and friable blood clot; blood also covered the spinal cord as low as the sixth cervical vertebra.

The lungs contained very many small abscesses, containing thick pus and altered blood; there were many pyæmic abscesses also in the kidneys. The other organs presented no striking abnormalities, except that there was advanced fatty degeneration of the liver. *Staphylococcus aureus* was grown from the pus at the base of the brain, in the cavernous sinuses, and in the orbit.

This case does not fit into the categories mentioned. It was not an uninfected case, nor was it due to direct spread from the site of operation, as in mastoid cases. It was septicæmic, but the history suggests that there was a local lesion before the septicæmia. There may have been a sphenoidal sinusitis, followed by sphenoidal osteomyelitis, cavernous sinus thrombosis, and subsequent pyæmia. If so, it is possible that the anæsthetic was the match that fired the train.

DIAGNOSIS

Signs and symptoms vary as the position of the lesion varies, and are modified by the condition of the patient; they may be masked by severe infection. The commonest site is the superior longitudinal sinus, usually the middle portion (Byers and Hass[3]), so that venous congestion of the cerebral cortex, especially the Rolandic areas, occurs early, and is followed by thrombosis. . Consequently motor symptoms are frequent, in post-operative and other cases. Later, softening of the brain occurs and hæmorrhage takes place, giving further symptoms. Drowsiness and vomiting are common, though in Case 4 there was extreme excitement.

Untoward signs, in these cases were first noticed at intervals varying from a few hours to two weeks after the operation, and there was no significant difference in this respect between infected and uninfected cases.

SUMMARY

Post-operative intracranial thrombosis occurs rarely in childhood, except as a local complication of mastoiditis. It occurs in septicæmia (usually streptococcal); possibly in toxæmia; by local spread from an infected air sinus; and in uninfected cases. Six cases from post-mortem records, and two personally observed, are described. Four of the operations were abdominal (2 herniotomies) and 4 were buccal (3 cleft palates). Three of the latter and only one of the former group were infected. The superior longitudinal sinus was the most frequently involved (5 cases).

My thanks are due to the surgeons and physicians named for permission to describe their cases, to the medical staff of the Hospital for Sick Children for permission to use the post-mortem records, and to Dr. R. W. B. Ellis for advice and help.

FAT NECROSIS ASSOCIATED WITH PERFORATED DUODENAL ULCER

By Michael J. Smyth, B.Sc., M.Ch. N.U.I., F.R.C.S. Eng.

SURGEON TO HOSPITAL OF SS. JOHN AND ELIZABETH, AND ASSISTANT SURGEON TO THE GORDON HOSPITAL FOR RECTAL DISEASES; FORMER FIRST SURGICAL ASSISTANT, LONDON HOSPITAL

Fat necrosis of the omentum and mesentery is so constantly associated with acute pancreatitis that many surgeons accept its discovery at operation as conclusive evidence of acute inflammation of the pancreas. The condition has been found, however, in connexion with acute perforation of a duodenal ulcer,[1] and also in cases of perforation and rupture of the small intestine,[2] as well as in a case where the cause was not discovered [3] (though the possibility of a leaking duodenal ulcer in this particular case was not excluded). In all of these cases the pancreas was found to be unaffected. While it is clear, then, that acute pancreatitis is responsible for most cases of fat necrosis, it is evident that there are many other conditions which produce it, and hasty inference must not be drawn from its presence. Furthermore, it is to be noted that in acute pancreatitis the peritoneal exudate is blood-stained, a factor which is helpful in arriving at the diagnosis before actual examination of the pancreas. To quote Lord Moynihan, "Whatever doubts may have been previously felt as to the nature of the disease, they are at once resolved when these two conditions, fat necrosis and sanguineous exudate, are found."[4]

The association of fat necrosis with perforation of a duodenal ulcer is rare, if we are to judge by published records; but I believe it is not unusual to find at autopsy small areas of fat necrosis near the site of perforated duodenal and perforated gastrojejunal ulcers.[5] Why this should be so is not clear, particularly as the condition is so seldom found at operation. A short review of the factors involved in producing fat necrosis may help to suggest an explanation.

Fat necrosis of omentum and mesentery is due to the action of two ferments, trypsin and steapsin, contained in the pancreatic juice. Steapsin splits the fat into fatty acids and glycerin, and the fatty acids combine with calcium salts to form calcium soap. It appears that this action can only take place after the death of the cell, caused by trypsin. Again, the extent of the conversion is governed by the activity of the pancreatic secretion, which is variable and dependent upon its content of trypsinogen and steapsin, and on the conversion of trypsinogen into trypsin. It is possible, then, for pancreatic secretion to escape into the abdominal cavity and cause little or no fat necrosis, though such a result is unlikely. In typical cases of acute pancreatitis, the condition shows itself as small white patches of fat necrosis dotted here and there over the omentum and mesentery, the patches being roughly round in shape and not more than a few mm. in diameter, unless by chance some of them coalesce to a larger size. In the early stages they are confined to the tissues of the lesser sac, but later they may be found widespread throughout the abdomen and in the subperitoneal fat. They have been found post mortem in the subpleural, subpericardial, and subcutaneous tissues, and even in the medulla of bones—such remote complications being explained by absorption of pancreatic ferments into the lymphatic and general circulation, as well as by actual embolism of pancreatic cells.[6]

Under normal circumstances, trypsinogen is converted into trypsin by the action of the enterokinase of the small intestine, and it may be asked how this conversion is brought about in cases of acute pancreatitis. Mellanby and Woolley (quoted by Walton)[6] have shown that *Bacillus coli* and other organisms are as capable of bringing about conversion of trypsinogen into trypsin as enterokinase. In fact one of the explanations of the acute fulminating condition which develops in the pancreas is that trypsinogen is converted into trypsin by micro-organisms which have gained a footing in the pancreas, and that trypsin then proceeds to digest the pancreatic cells themselves. In any event the eruption in the pancreas is so great that the escape of pancreatic secretion from the grossly damaged pancreas is inevitable and no doubt profuse, and, as we have seen, if allowed time to develop will have widespread effects.

In cases of perforation of duodenum and intestine the escape of pancreatic secretion is not so assured. Here much will depend upon the amount of free or unutilised pancreatic secretion in the bowel at the time of perforation, and also on the proximity of such secretion to the site of perforation; for we may take it that following the shock of perforation, the normal function of the pancreas and its ducts, as well as that of the duodenum and intestine, will be in abeyance. When one considers that fat necrosis is found occasionally, post mortem, in cases of perforated duodenal and gastrojejunal ulcers, and that it is seldom found at operation, it seems likely that operation is undertaken before the condition of fat necrosis has had time to develop. In Richter's case of fat necrosis following the perforation of a duodenal ulcer, 28 hours had elapsed before the time of operation, and in the case recorded here the interval was 36 hours.

The patient, a barman aged 46, was admitted to the North Middlesex Hospital at 10 P.M. on July 21st, 1925. He was *very ill and unable to give much history*. The main facts were that about 11 A.M. on the previous day he was seized with acute abdominal pain and vomited. His doctor ordered medicine which was taken with relief. After one and a half days in bed, with only sips of water to relieve thirst, another doctor ordered his removal to hospital.

On admission the temperature was 101·4° F. and the pulse-rate 126. The abdomen was distended, tender and rigid; there was no movement on respiration. Laparotomy was performed through a right mid-abdominal paramedian incision. The peritoneum was found to be œdematous and the abdominal cavity flooded with seropurulent fluid. Fat necrosis of the omentum was at once apparent and the incision extended upwards. The pancreas proved to be normal to palpation but a perforation was discovered on the upper anterior surface of the first stage of the duodenum. This was closed and the abdomen drained.

The patient was admitted to the London Hospital three months later for investigation. Mr. James Sherren opened the abdomen through the scar of the previous operation and found the omentum adherent to the upper part of the abdominal wound. The adhesions were cleared. The omentum was otherwise normal in appearance and there was no sign of previous fat necroses. The site of the perforation of the duodenal ulcer was identified, and a small piece of unabsorbed catgut was found protruding from the surface of the duodenum. The pancreas, exposed through gastrocolic omentum, was normal to inspection and palpation. Posterior gastrojejunostomy was performed, and the patient was discharged from hospital towards the end of the third week. For ten years he has enjoyed excellent health; he now runs a grocer's shop and says he works 12 hours a day.

In this case the patches of fat necrosis were much larger than those usually seen in acute pancreatitis—some of them being more than an inch in diameter—and they were extensively distributed over the surface of a large and well-nourished omentum. Three months later, however, they had disappeared without trace. A portion of the omentum excised at the time of the first operation was examined by Dr. T. H. C. Benians, who described the specimen as one of "typical fat necrosis of the omentum."

I am grateful to Mr. Sherren for permission to publish the details of the second operation.

A GIFT FOR RADIUM.—King Edward's Hospital Fund for London has received from Mr. Roger Parr a donation of £10,000 as a Jubilee gift to its radium fund. In 1929 Mr. Parr gave £10,000 towards the purchase of the stock of radium which the Fund places out on loan to hospitals. His present gift is to facilitate schemes which are at present being worked out by the King's Fund for increasing the usefulness of this radium.

A FATAL CASE OF ELECTROCUTION

By A. H. D. Richmond, M.B. Edin.
HON. ANÆSTHETIST, GRIMSBY AND GENERAL HOSPITAL

JELLINEK[1] in 1912 described the factors which play an important part in electrical accidents and drew attention to the influence of resistance, voltage, amperage, earth contact, and the mental condition of the victim at the moment of the shock. The traumatic results of electrocution are more or less governed by the path of the current, whether direct through the body or indirect over its surface. The effect of currents of high voltage on the nervous system has lately been described by Critchley[2] and Pritchard.[3]

A case is recorded below in which a healthy male succumbed to an alternating current of 590 volts despite prompt attempts at resuscitation. These cases of electrocution are as yet uncommon in this country.

A young engineer in an electricity works was found lying unconscious on the ground some three feet from the guarded switchboard controlling a rotary converter. His duties included the starting and running up of this motor, and on the day of the accident he was seen walking down the room to perform this act. Shortly afterwards a fellow mechanic discovered him lying on the ground and artificial respiration was instituted, within about ten minutes, on the assumption that the victim had received an electric shock. Unfortunately the man never recovered consciousness and he was removed to hospital dead. Artificial respiration had continued for about 55 minutes.

POST-MORTEM FINDINGS

Autopsy was performed six hours after death, and a further examination twenty-four hours after death. The body was that of a young well-built and well-nourished male; height 5 ft. 10 in., and weight 12 st. approximately. Post-mortem lividity was well marked on the lower (dorsal) aspect; the features were congested and the superficial temperature of the body was still perceptible to the hand, although a clinical thermometer failed to register it.

Eyes.—The pupils were dilated, and running horizontally across the cornea and sclera of both eyes was a linear scar. The sclerotic of the right eye showed two hæmorrhages, medial and lateral, and the left sclerotic, one on the lateral aspect, in a line with the scars. The index-finger and thumb of each hand showed recent burns and these wounds demonstrated the points of contact, and that the victim must have grasped the live points firmly between the fingers and thumbs.

Right hand.—A small wound on the middle phalanx of the index-finger, and on the radial side of that finger there was an elongated lacerated wound which ran obliquely downwards from back to front and showed signs of blistering and charring. On the dorsum of the same finger there was a small circular char, similar in appearance to the burn caused by a lighted match head which has stuck to the skin after striking. On the thumb of the right hand a small linear scar ran longitudinally from the tip.

Left hand.—On the radio palmar aspect of the distal phalanx of the thumb there was a small triangular burn with a depressed centre. The index-finger showed an elongated wound similar to that of the right hand with the same characteristics (Fig. 1).

Examination of the *hands and forearms* showed a definite pale area of the skin extending from the thumbs and index-fingers and tapering down to a point towards the elbows. Externally there was no other evidence of injury.

Brain.—The dura mater showed numerous petechial hæmorrhages throughout the surface and towards the base of the skull there was a definite congestion of the blood-vessels and extravasation of blood. On the brain surface the sulci were marked by petechial hæmorrhages except one area at the superior extremity of the right fissure of Rolando, which by contrast was very pale.

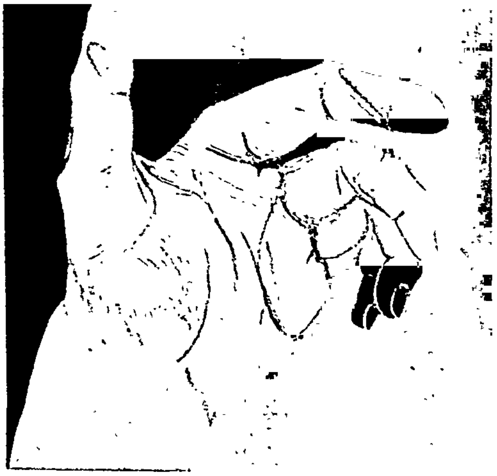

FIG. 1.—Sketch of left hand showing burns of thumb and forefinger.

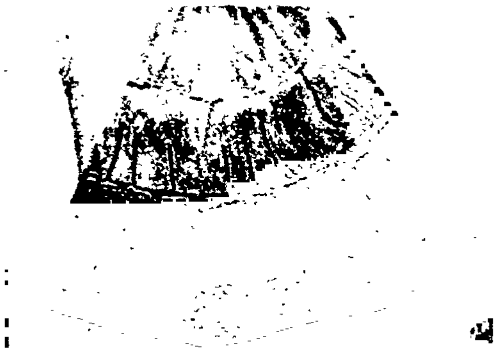

FIG. 2.—Section of loop of small bowel showing prominent lacteals and patch.

Further examination of this area revealed that the pia mater and the arachnoid had been stripped off the underlying brain tissue. At the anterior extremity of the second frontal convolution, right lobe, there was a small superficial hæmorrhage about the size of a sixpenny piece. No laceration nor evidence of disease of the brain tissue was found.

In the region of the *neck* there was marked congestion of the muscles and tissues. Tongue, trachea, and œsophagus were healthy but congested.

Thorax.—There were no adhesions between the pleural surfaces. The lungs were ballooned and mottled, but the surface was light in colour. Petechial hæmorrhages were seen on the costal and interlobular aspects. Along the lateral borders of both lungs were several subpleural hæmatomata. The blood in these hæmatomata was still fluid some twenty-four hours after death. On section the lungs showed congestion but no evidence of disease. The pericardium was normal and healthy, with a small amount of clear fluid present in the sac. Several petechial hæmorrhages were seen. The myocardium was also healthy; both ventricles contained a very small amount of dark fluid blood. All valves were patent and normal. The endocardium showed one or two minute petechial hæmorrhages; otherwise healthy.

Abdomen.—The stomach was small, empty, and normal. The liver, spleen, and kidneys were congested but healthy. On section of the spleen the blood ran out freely. The coils of the small intestine showed two features of interest apart from the petechial hæmorrhages, viz.: (1) The pearly-white appearance of the lacteals, which stood out on the surface of the bowel and mesentery. As they emerged from the muscular layer, these lacteals ran longitudinally to anastomose in pairs forming a main trunk which turned upward into the mesentery for a distance of one inch before disappearing in the deeper layers. (2) At the most dependent portion of each loop of the small bowel there was a definite patch of congestion about one and a half inches long on the surface opposite the mesenteric attachment. Further examination of these patches showed an apparent thinning of the muscular layer and general loss of tone, compared with the rest of the bowel (Fig. 2).

Blood.—The usual condition of the blood after electrocution was conspicuous in this case; the fluidity was general and remained so for at least twenty-four hours after the autopsy. A blood film showed no abnormality.

Microscopic examination of the skin of these burnt areas showed a gap in the superficial layer and vacuolation in the stratum corneum which was separated from the deeper layers (Fig. 3). In the centre of the burn, the structure of the stratum Malpighii was quite effaced, and the subjacent cellular tissue had its cell nuclei distorted into threads (Fig. 4). The blanching of the skin between the index-fingers and thumbs demonstrated the superficial or indirect path of the current.

THE INCIDENCE OF PROCTITIS IN GONORRHŒA OF FEMALES

By P. A. Clements, M.B. Durh.

SENIOR ASSISTANT MEDICAL OFFICER, VENEREAL DISEASE DEPARTMENT, ST. THOMAS'S HOSPITAL, LONDON; AND

K. E. A. Hughes, M.R.C.S. Eng.,

ASSISTANT PATHOLOGIST IN THE DEPARTMENT

Gonococcal infection of the rectum as a complication of gonorrhœa in women does not appear to have attracted much attention in this country, and probably if the medical officers of our venereal disease treatment centres were asked to state their opinion as to its incidence, most of them would declare it to be negligible. The reason is that in the great majority of cases the condition causes practically no clinical sign or symptom. In this respect we may say at once that our experience coincides exactly with that of C. L. Martin,[1] whose paper appeared whilst we were collating the results of the investigation reported here.

Our attention was drawn to the subject of gonococcal proctitis a few years ago by Dr. Vuletic, of Prague. During a visit to the V.D. Department, St. Thomas's Hospital, Dr. Vuletic said that in continental clinics it had been found to be a very common complication of gonorrhœa in females. Our scepticism about its frequency in this country was met by Dr. Vuletic's suggestion that laboratory tests of rectal secretion might lead to a different opinion, and a small series of specimens taken then showed us that in this matter we had been in a fool's paradise. Some months later we commenced a systematic investigation to ascertain the incidence of proctitis in our female patients with gonorrhœa, and the results are reported below.

The cases comprising the present series are a random sample, in that one of us (P. A. C.) whenever an opportunity occurred took specimens from the rectum of any female under examination on first attendance, or under treatment for gonorrhœa, or undergoing tests of cure following treatment for gonorrhœa.

METHOD OF INVESTIGATION

The procedure was as follows:—

Collection of Material.—After external cleansing and insertion of a plug into the vagina to prevent any possibility of contamination with vulvovaginal secretion, a well-made platinum loop was passed through the anal canal in such a way as to rub along the anterior wall of the rectum, from which the specimen was collected. In the majority of cases (37 out of 69 that showed the presence of gonococci) the loop collected no visible secretion; in 8 it collected obvious pus, and in 22 only a mucoid secretion. On withdrawal a smear of the secretion was made on a microscope slide which was stained by Jensen's modification of Gram's method. Another specimen was immediately spread on the culture medium which in our experience has been found most suitable for isolating the gonococcus in these circumstances.

Culture Medium.—In a search for the most suitable medium one of us (K. E. H.) had tried the following: (1) Hydrocele broth, pH 7·6, containing various quantities of telluric acid and/or brilliant green, as restrainers of growth of *B. coli*. (2) Broth containing various quantities of a highly potent anti-*B. coli* serum. (3) Slopes of hydrocele agar, pH 7·6 in tubes of 1 inch diameter and providing a surface area of about 3½ square inches. (4) The same medium in Petri dishes providing a surface area of about 9½ square inches. Of all these the two first were useless and the last proved by far the most satisfactory; it was therefore employed in all the cases composing the present series.

In inoculating the plated medium the charged loop was made to draw series of closely set parallel lines in one direction and then a similar series at right angles to the first. Incubation was carried out at 37° C. for 48 hours, the plates being inverted to prevent water of condensation falling on the medium.

Recognition of Gonococci.—In preliminary detection of colonies of gonococci use was made of the oxidase reaction of J. W. McLeod and J. Gordon.[2] About 1 c.cm. of a 1 per cent. aqueous solution of dimethyl paraphenylene diamine hydrochloride was allowed to flow over the surface of the medium, the plate being slightly sloped to get rid of surplus reagent. After about five minutes smears were made from any pink colonies and stained by Jensen's modification of Gram's method. A diagnosis of gonococci was made on the strength of the organism being Gram-negative and having the morphological characteristics of gonococci. In positive cases the number of colonies varied from one (in several instances) to uncountable and giving the appearance of a pure culture (in two instances).

With regard to the question whether or not it is an advantage to employ both slide and culture the following were the results of 240 parallel tests. In 42 (17·5 per cent.) both smear and culture were positive; in 28 (11·7 per cent.) only the culture was positive; and in 11 (4·5 per cent.) only the smear. The employment of both methods therefore resulted in gonococci being discovered by one or both in 81 (33·7 per cent.) of the cases as compared with 29·2 per cent. if only cultures had been used and 22 per cent. if only slides.

RESULTS

The number of cases investigated in this way was 160. Their condition on first attendance at the clinic had been as follows:—

Category.	Description.	
(G.1)	With gonorrhœa of less than two weeks' duration ..	46
(G.2)	,, ,, ,, 2 to 4 ,, ,, ..	19
(G.3)	,, ,, ,, 4 to 52 ,, ,, ..	59
(G.4)	,, ,, ,, more than one year's ,, ..	4
(G.5)	With a history of gonorrhœa but no present bacteriological evidence of it	11
(N.V.)*	With no evidence of venereal disease	21

* This category for the purpose of this paper includes a few syphilis cases.

The cases were examined at various times after first attendance as shown in the Table. The figures in this Table relate to the results of the first examination of the rectal secretions and therefore represent a minimal incidence in the material examined.

Table showing the number of months after first attendance when the rectal examination was carried out, and the results

Category on first attendance.	No. of cases.	Examination of rectal secretion carried out							
		On first attendance		After first attendance during					
				1st month.		2nd to 5th month.		6th month or later.	
		Pos.	Neg.	Pos.	Neg.	Pos.	Neg.	Pos.	Neg.
G.1 ..	46	2	2	4	2	14	13	2	7
G.2 ..	19	1	1	6	3	2	4	1	1
G.3 ..	59	7	9	16	2	11	11	1	2
G.4 ..	4	1	1	0	0	0	0	1	1

The Table shows that in 128 cases with evidence in slide and/or culture of gonorrhœa 69 were found by the same methods of examination to be suffering from gonorrhœal proctitis. In only 2 of these cases did the patient complain of any local discomfort, and in only 8 was there any sign of purulent discharge. In 8 of the positive cases the patients were under observation and tests of cure after treatment for gonorrhœa of the genito-urinary passages, and neither at the time of the rectal examination nor later showed gonococci in the urethral or cervical secretions. These patients would therefore have been discharged as cured but for the rectal examination.

---

[1] Jour. Amer. Med. Assoc., 1935, civ., 192.

[2] Jour. Path. and Bact., 1928, xxxi., 185.

In 7 cases gonococci were never at any time found elsewhere than in the rectum. Salient points in these cases were as follows:—

1. Pregnant; sent for examination on account of a Bartholin abscess, and to be tested for fitness for admission to a maternity home; gonococcal complement-fixation reaction ++ (1/1).
2. Sent for examination because husband suffering from gonorrhœal rheumatism; complement-fixation reaction ++ (1/5).
3. Husband suffering from gonorrhœa; gonococcal complement-fixation reaction negative.
4. Sent by consort who had gonorrhœa of seven days' duration; gonococcal complement-fixation reaction ++ (1/5).
5. Attended with secondary syphilis; gonococcal complement-fixation reaction ++ (1/1).
6. History of treatment for gonorrhœa in another clinic; complement-fixation reaction ±.
7. Contact under treatment for acute attack; complement-fixation reaction negative.

In 5 of these cases the positive complement fixation would probably have prevented discharge of the cases, but in the remaining 2 only the rectal examination discovered the infection.

TREATMENT

In 10 cases nothing was done locally, and examination repeated from one to seven months afterwards gave a negative result in only 1. Most of the cases were treated at first by irrigation with potassium permanganate, 1/4000 to 1/8000, but this proved very disappointing, the majority of the patients being found to be still infected after from one to five months of such treatment. On the other hand, irrigation with acriflavine 1/5000 seemed as a rule to be effective usually within about a month; though further observation will be needed to determine in what proportion of these cases the infection has really been eradicated.

SUMMARY

(1) Of 160 cases suffering from gonorrhœa of the genito-urinary passages, or under tests of cure, or under suspicion, gonococci were found in the rectal secretion of 69. (2) In the great majority obvious signs and symptoms were absent. (3) By cultural methods an important proportion of cases are discovered which would be overlooked if tested only by smear on microscopic slide. (4) In 8 cases under test of cure gonococci were not found in the secretions of urethra and cervix either at the time of the rectal examination or later. (5) In 7 other cases examined under suspicion for one reason or other no gonococci were ever found in secretions from the genito-urinary passages. (6) Gonorrhœal proctitis does not appear to be self-limited; treatment by irrigation with potassium permanganate proved disappointing, but acriflavine 1/5000 seemed satisfactory. (7) Microscopical and cultural examination of the rectal secretion is clearly required for every female in whom there is any question of a gonococcal infection.

We wish to thank Colonel L. W. Harrison, director of the department, for permission to publish this paper.

THE ERYTHROCYTE SEDIMENTATION-RATE

A COMPARISON OF THE METHODS COMMONLY EMPLOYED FOR ITS DETERMINATION

By G. E. Beaumont, D.M. Oxon., F.R.C.P. Lond.
PHYSICIAN WITH CHARGE OF OUT-PATIENTS, MIDDLESEX HOSPITAL, LONDON; PHYSICIAN TO THE BROMPTON HOSPITAL; AND

J. W. Maycock, M.B. Camb.
HOUSE PHYSICIAN TO THE BROMPTON HOSPITAL

The estimation of the sedimentation-rate of the erythrocytes is firmly established as a valuable index of progress in certain diseases—notably pulmonary tuberculosis. Three methods of estimation are in general use at the present time: the Westergren method, the modified method of Zeckwer and Goodell, and the "micro-method." Reports on the sedimentation-rate are apt to perplex the practitioner, since often they do not state the method employed, the duration of the test, and whether the red cells or the plasma are measured. For example, the report may read "the red cells drop 26 mm.," or "sedimentation-rate 8·7," or "blood sedimentation-rate 13 per cent." The first report (26 mm.) indicates that the test has been performed by the Westergren method, and that the one-hour reading is plasma 26 mm. and red cells 174 mm. The figure 8·7 means the test has been carried out by the modified Zeckwer and Goodell method, and that the one-hour reading is red cells 8·7 parts, plasma 1·3 parts. The figure 13 per cent. is reached by a micro-method one-hour or half-hour reading, the plasma occupying 13 parts and the red cells 87 parts.

It is our purpose to describe briefly the three methods to show the relationship between them, and to indicate some advantages or disadvantages of each. A comparison of the three methods performed at the same time and under the same physical conditions was carried out on 10 patients at the Brompton Hospital, and the results are tabulated below.

The Westergren method,[1] a modification of the Fahraëus technique,[2] is performed in a glass tube 30 cm. long and 2·5 mm. in bore, graduated from below upwards from 0 to 200 mm. Blood is withdrawn from a vein, and mixed in a small test-tube with sodium citrate (3·8 per cent.) in the proportion of 4 parts of blood to 1 part of citrate solution. The citrated blood is then sucked up into the tube to the 200 mm. mark; the lower end is closed by inserting the tube into a rubber stopper, and the tube set perpendicularly in a stand. The reading is taken at the end of one and two hours, the column of clear fluid above the sedimented corpuscles being measured. A normal reading was considered by Westergren to be 3 mm. of clear fluid at the end of one hour. For purposes of comparison the reading can be given as a percentage by dividing it by 2, the result being expressed as mm. of supernatant fluid per cent.

The method used by us at the Brompton Hospital is a modification of that described by Zeckwer and Goodell.[3] The sedimentation tube has a bore of 0·75 cm., and it is marked in ten divisions each of 1 cm. Sodium citrate (3·8 per cent.) is placed in the tube to the 2 mark. About 5 c.cm. of blood is drawn from a vein, and ejected from the syringe into the tube containing the sodium citrate to the 10 mark. In this method the height of the column of sedimented corpuscles at the end of one and two hours is read in centimetres, and the tenths of a centimetre by placing a millimetre scale against the tube. The column of supernatant fluid is not recorded. A normal reading is 9·7 cm. of corpuscles in one hour. The reading can be made comparable with those of other methods by subtracting it from 10, and multiplying the result by 10, thus giving so many mm. of supernatant fluid per cent.

A third method is the "micro-method." The tube used is a capillary pipette of thick glass, about 6 in. long, whose bore is 1·13 mm., and graduated from above downwards in mm. from 1 to 100. The patient's finger is pricked, after warming it in hot water, and eight drops of blood are sucked into a special teated pipette; the blood is then mixed in a small test-tube with two drops of 3·8 per cent. sodium citrate solution. The citrated blood is then sucked into the capillary pipette to the mark 1, and the tube set in a water-bath at a temperature of 37° C. The reading of supernatant fluid is taken at the end of half an hour by some observers and at one hour by others. The final reading is expressed as so many mm. of supernatant fluid per cent. Normal readings are between 0·5 and 4·0 per cent. for men, and between 1 and 8 per cent. for women after half an hour.

Commenting on the three methods, we think that the Westergren method has the advantage that it or some modification of it is the most extensively used of all three, especially on the continent, and therefore the significance of its readings are more likely to be widely known. It is possibly more accurate than the modified Zeckwer method, since finer readings can be taken as a smaller column of blood is employed, but this does not seem to us an overwhelming advantage, the test being essentially a somewhat rough estimate of activity in pulmonary tuberculosis, and the value lying largely in the serial readings obtained in individual cases. The modified method of Zeckwer and Goodell has the great advantage of simplicity and it is sufficiently accurate for practical purposes. With regard to the "micro-method," the advantage would seem to be that it can be used when vein puncture is impossible. But the test is, in our opinion, not so easy to carry out, for it is sometimes difficult to obtain the requisite amount of blood by pricking the finger, and the technique is more complicated than in the other methods.

Table giving Comparison of Sedimentation-rates by Three Methods (after one hour)

—	Westergren method. 200 mm. tube.	Modified Zeckwer and Goodell method. 10 cm. tube.		Micro-method. 100 mm. tube.
	Plasma mm. (and mm. per cent.).	Corpuscles cm.	Plasma mm. per cent.	Plasma mm. per cent.
1	50 (25)	7·0	30	24
2	36 (18)	7·4	26	18
3	12 (6)	9·2	8	9
4	10 (5)	8·9	11	14
5	64 (32)	7·0	30	11
6	5 (2·5)	9·4	6	10
7	4 (2)	9·6	4	3
8	10 (5)	9·5	5	8
9	4 (2)	9·8	2	5
10	6 (3)	9·4	6	2

The Table shows that there is no constant discrepancy between the readings of the methods. The value of the sedimentation test lies in the comparison of readings, by the same method, from week to week, and whichever method is used, this is found to be a fairly good criterion of progress or retrogression. It would undoubtedly be an advantage if one method could be used universally; the test would then have more widespread significance.

Clinical and Laboratory Notes

A CASE OF AGRANULOCYTOSIS

By C. Rickword Lane, B.M. Oxon., D.P.H.

PATHOLOGIST TO THE HAMPSTEAD GENERAL HOSPITAL

The following case is reported to draw further attention to this condition, which is probably considerably commoner than is generally imagined.

The patient, a single woman aged 59, was admitted to the Hampstead General Hospital in December, 1934. On the day before admission she had noticed a small pimple on the lower lip just below the angle of the mouth on the left side; on admission there was a lesion about the size of a farthing in this situation, dark bluish-black in colour, and surrounded by moderate œdema and redness. The suspicion of anthrax arose and I was asked to examine it from this point of view. Material was scraped from the surface, a procedure which proved to be almost painless, and on examination revealed the presence, in pure state and considerable numbers, of a small actively motile Gram-negative bacillus.

The general condition at this time was good, though the temperature was 103·4° F. and the pulse-rate 120. There was no ulceration of the throat, but she was found to have a completely healed perforation of the palate; there was also a depressed scar over the left great trochanter. Apart from these two findings nothing of note was discovered. She stated that about nine months previously she had had a throat infection followed by an abscess in the thigh which had been treated at another hospital with complete recovery, her general health having subsequently been good.

The history obtained from this hospital was that she had been admitted with a severe membranous pharyngitis from which pneumococci had been grown and had later developed an abscess over the great trochanter, the infecting organism not being ascertained. Though gravely ill she had recovered but with a perforation of the palate and the scar we observed. The case had been regarded as obscure and no definite diagnosis was made.

That evening the local lesion was excised. Later in the evening the possibility of the case being one of agranulocytosis occurred to me and the following morning a leucocyte count revealed: white blood-cells, 1000 per c.mm., with no polymorphs or eosinophils, lymphocytes, 84 per cent.; and mononuclears, 16 per cent. The patient was now gravely ill. The excision wound showed a very remarkable appearance, with bluish-black necrotic tissue round the excision edge and outside this spreading œdema. The culture from the original lesion gave a pure growth of a motile Gram-negative bacillus producing a pink growth on ordinary agar; it subsequently proved to be a typical *B. prodigiosus*. A blood culture taken at the same time as the leucocyte count grew a pure culture of the same organism within twenty-four hours.

Pentnucleotide therapy was instituted as soon as the drug could be obtained; 20 c.cm. were given this day and again 20 c.cm. the following morning, on each occasion by the intramuscular route. A blood transfusion of 500 c.cm. plus citrate was given later on the same day as the first dose of pentnucleotide. On the following morning she was in extremis, an intravenous saline was administered, but she died about 2 P.M. The temperature was maintained between 101·5° and 104° F. during the course of the illness and the pulse-rate at 120, rising to 130 before death.

Histological examination of the tissue removed at operation showed a generalised necrobiosis of the epithelium, corium, and subjacent fat with practically no tissue reaction even at the edge of the necrotic area, what reaction there was being entirely mononuclear. The necrotic area was packed with Gram-negative bacilli.

At post-mortem examination the ordinary changes associated with septicæmia were well in evidence and the kidney and liver contained scattered collections of Gram-negative bacilli without tissue reaction round them. There were no polymorphs in the splenic pulp; the femoral marrow was chiefly fatty even in the head; the rib marrow was pink. In both femur and rib sections showed that red cell production was normal; but though some myeloblasts and myelocytes were found there were no formed polymorphs.

The points of interest in this case are: (1) the previous illness, which one may reasonably assume to have been agranulocytic angina, as the condition is known to be recurrent in some cases. If this opinion is correct a new cause of perforation of the palate is demonstrated. (2) The peculiar site of the lesion and the fact that where secondary infection was not so likely to occur as in the throat the infection was pure. The organism responsible is generally regarded non-pathogenic and of such restricted distribution that it is difficult to imagine how she came by it, particularly in pure state. This seems to dispose of any idea that any particular organism is associated with this disease and to demonstrate the importance of the "soil." The examination of the marrow supports the contention that the mechanism is a failure of maturation of the myelocyte comparable to the maturation failure in pernicious anæmia.

No history of the patient having taken amidopyrin in any form could be obtained; but the facts had to be got mainly from her relatives, her medical attendant, and her employer. When the diagnosis was made the patient was too ill to be able to fix her attention sufficiently to give a convincing answer.

THROMBOSIS OF THE ENTIRE AORTA

IN A WOMAN AGED TWENTY

By J. Gough, M.D. Wales

LECTURER IN PATHOLOGY, WELSH NATIONAL SCHOOL OF MEDICINE

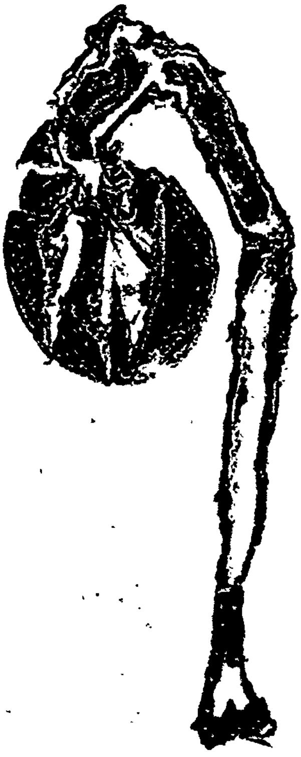
The following case is recorded because it showed the extremely unusual feature of a thrombus extending the whole length of the aorta.

Clinical History.—When admitted to hospital, eighteen weeks before death, the patient, a woman aged 20, had been suffering from dyspnœa and pain in the chest for eighteen months. She was found to have hypertrophy of the left ventricle without any apparent valvular lesion; the systolic blood pressure was 170 mm. Hg; the urine contained a large amount of albumin, together with blood-cells and fatty casts.

A hemiplegia occurred suddenly 10 weeks after admission to hospital, and there was gradual recovery from this. Eight weeks later there developed a sudden and complete flaccid paralysis of the lower limbs. The legs were at first completely white, but later they became bluish and showed large ecchymoses. There was complete loss of sensation in the lower limbs. On the following day the patient suffered severe abdominal pain and died some hours after passing a large quantity of blood per rectum.

Post-mortem Findings.—In the aorta, about half an inch above the valve, was found a shallow pouching toward the right side. On the outer aspect of this the pericardium was adherent. From this point a white and mixed fibrin thrombus extended the whole length of the vessel. In the arch and in the descending thoracic aorta the lumen was almost filled and only a narrow irregular channel was left for the passage of blood. Below the origin of the superior mesenteric artery it was completely obliterated. The thrombus in the arch was dense white and adherent, but below this it was mixed red and white and much less adherent. The aortic wall showed extensive calcification.

The heart was slightly enlarged and showed hypertrophy and some dilatation of both ventricles. The valves were quite normal. There was a layer of antemortem thrombus in the left ventricle near its apex. This thrombus was easily stripped from the underlying mural endocardium. Infarcts were present in the spleen and kidneys. There was extensive infarction of the small intestine due to the mouth of the superior mesenteric artery being occluded by the thrombus in the aorta. A small cystic softening was found in the brain involving the left lenticular nucleus and lying almost completely across the internal capsule.



The heart and aorta.

Histological Findings. — The aorta showed widespread and severe damage. The media was very much thinned and its elastic fibres were fragmented and granular. They were interrupted by areas of round-cell infiltration having a characteristic perivascular distribution and giving an apparently typical picture of syphilitic aortitis. The intima was thickened and in its deeper parts there were extensive areas of fatty degeneration. Large plaques of calcification involved both the intima and the adjacent media. The thrombus showed organisation which was most advanced in the arch. The thrombus present in the left ventricle showed early organisation and was apparently not as old as that in the arch of the aorta. The myocardium underlying the thrombus in the heart appeared normal.

The lesion in the aorta appears to be one of syphilitic aortitis accompanied by a very severe degree of atheroma. The mode of development of the thrombus was not obvious. There was no gross aneurysm formation in which the process could have started. There was however a slight pouching of the aorta in the ascending part in which the thrombosis probably commenced.

This case is unusual not only in the extent of the thrombus but also in the fact that although occurring in a young subject the thrombosis arose as a direct result of arterial disease. Aortic thrombosis in young adults is usually a result of emboli from the heart becoming impacted at the bifurcation of the aorta. L. Desclin[1] however has described a case of aortic thrombosis in a woman aged 19 in which the thrombosis was due to a primary aortitis. In his case the thrombus was limited to the ascending part of the arch and the aortitis was of coccal origin and the inflammation practically limited to the intima. In the present case there was no evidence of acute infection and nothing was found which might have contributed to the thrombosis apart from the chronic aortic lesion.

DIPHTHERIA FORMOL TOXOID AND THE MOLONEY TEST

By Robert Swyer, M.R.C.S. Eng., D.P.H.
SENIOR ASSISTANT MEDICAL OFFICER, NORTH WESTERN HOSPITAL, LONDON COUNTY COUNCIL

In 1929 Moloney and his co-workers [1] stated that "the results of tests on 50 voluntary subjects showed that *the greater the sensitivity to the intradermal* injection (of 1 in 10 dilution of anatoxine) the more marked is the reaction both local and general following the subcutaneous injection of anatoxine. If the diameter of the redness following the intradermal test is less than 10 mm. no marked local or general reaction followed the prophylactic dose of 0·5 c.cm. of anatoxine." In 1928 the same workers [2] recommended a dosage of toxoid depending upon the size of the intradermal test reaction as follows:—

Intradermal injection of 0·2 c.cm. of 1/10 dilution of diphtheria toxoid. (*a*) Redness up to 20 mm. (*b*) Redness over 20 mm. without œdema. (*c*) Pronounced redness + œdema.

Group (*a*)	to have 3 injections of	0·1 c.cm. toxoid	At intervals of 3 weeks.
,, (*b*)		0·02 ,, ,,	
,, (*c*)		0·01 ,, ,,	

It was with a view to confirming the first statement and deciding upon the advisability of varying the dosage as recommended in 1928 or of using some other prophylactic in Moloney-positive reactors that the following investigations were undertaken.

The subjects were recruits to the nursing staff at the North Western Hospital. All were Schick- and Moloney-tested on joining. The Moloney reaction was carefully read and recorded at 24, 48, and 72 hours, and it was found that in almost all cases it was at its height at 48 hours. Reactions were placed in three groups according to size: Group 1 showing an area of redness up to 10 mm. in diameter, Group 2 between 10 and 30 mm., and Group 3 above 30 mm. All Schick-positive reactors were inoculated with formol toxoid; no variation in the procedure or dosage of the prophylactic being made whether the subject was a Moloney-positive or negative reactor. Formol toxoid reactions were divided into local and general; each of these divisions being sub-divided into three groups—i.e., slight, moderate, and severe;

A slight local reaction = local redness up to 1 inch diameter.
A moderate ,, ,, = ,, ,, from 1 to 4 inches.
A severe ,, ,, = redness above 4 inches diameter + swelling.

Temperature was used as the main index of severity of general reactions. Each case was seen by me personally on each of the three days following toxoid inoculations and the temperature taken.

Temperatures between normal and 100° F. were classed as slight.
Temperatures between 100° F. and 102° F. were classed as moderate.
Temperatures above 102° F. were classed as severe.

In all 57 cases were observed, of which 23 were Moloney-positive and 34 Moloney-negative. The results obtained are shown in Tables I. and II.

Two nurses were taken off duty as a result of reactions. One of these had a slight Moloney, but a severe local reaction; the other had a severe Moloney and a severe local reaction.

Table I.—*Positive Moloney Reactors*
(23 cases = 40 per cent.)

Size of Moloney test.	Cases.	Reactions to formol toxoid inoculations.	
		Local.	General.
Up to 10 mm. diameter (8 cases).	1	—	—
	3	Slight.	—
	1	Moderate.	—
	2	Severe.	—
	1	Moderate.	Moderate.
Between 10 and 30 mm. diameter (10 cases).	2	Slight.	—
	1	,,	Slight.
	1	Moderate.	—
	2	,,	Slight.
	1	,,	Moderate.
	2	Severe.	—
	1	,,	Moderate.
Above 30 mm. diameter (5 cases).	1	—	Slight.
	1	Moderate.	—
	1	Severe.	—
	1	Moderate.	Slight.
	1	Severe.	Severe.

Table II.—*Negative Moloney Reactors*
(34 cases = 60 per cent.)

Cases.	Reactions to formol toxoid inoculations.	
	Local.	General.
17 ..	—	—
10 ..	Slight.	—
2 ..	Moderate.	—
2 ..	Slight.	Slight.
1 ..	Moderate.	,,
1 ..	Severe.	Moderate.
1 ..	—	Slight.

The most striking fact which emerges from an examination of the above Tables is that some sort of reaction is to be expected in 50 per cent. of Moloney-negative reactors, and in some 12 per cent. this reaction will be of more than trifling severity. A positive Moloney, however, does indicate the practical certainty of a reaction of some sort following toxoid inoculation. It will also be seen from the Tables that the size of the Moloney is not a true index of the severity of the reaction either local or general to be expected, all grades of severity appearing in each group of Moloney reactors.

Although the series is a small one (57 cases) the figures are strictly comparable with those of Moloney (50 cases). As a result of the investigation no action is to be taken with regard to varying the dosage of toxoid according to size of Moloney reaction.

Conclusion.—The Moloney test has been applied to 57 young adults (nurses). The results suggest that the test is not an accurate index either of the liability to, or severity of, the reactions to be expected in adults after the injection of formol-toxoid.

National Institute of Industrial Psychology.—A vacation course in the administration of Binet-Simon tests of intelligence will be held at the Institute of Education, London, from August 14th to 24th. The course is intended for doctors and nurses and others concerned with mental hygiene, and particulars can be obtained from the National Institute of Industrial Psychology, Aldwych House, London, W.C.2.

REVIEWS AND NOTICES OF BOOKS

Injuries and their Treatment

By W. ELDON TUCKER, B.Chir. Camb., F.R.C.S. Eng., Surgeon to St. John's Hospital, Lewisham; Surgeon to the London Clinic for Injuries, Baker-street; late Registrar, Royal National Orthopædic Hospital. London: H. K. Lewis and Co., Ltd. 1935. Pp. 174. 9s.

THE pathology and treatment of injuries to the soft structures of the body is a subject which never seems to arouse much interest among the juniors in hospital circles. The student or resident who is bored with sprains and strains, and does not bother to learn much about their treatment, gets an unpleasant shock when he finds how much importance he is expected to attach to such injuries in general practice. Sir Humphry Rolleston notes in a preface to this volume that Mr. Eldon Tucker's interest in his subject and his knowledge have been acquired in a very practical way—by treatment of injuries in fellow athletes. Many text-books have been written dealing with a special form of treatment, such as massage, electrotherapeutics, or graduated muscular contractions; Mr. Eldon Tucker examines *all* the methods that he considers useful, and in a chapter at the beginning of his book compares the results to be obtained by each. He is then in a position to prescribe the suitable combination of methods for each injury in turn. Particularly welcome are the details of joint manipulation with comments on an appreciation of its advantages and dangers at the various stages of repair after injury. Too prolonged rest is held by the author, as by many of his colleagues, to favour fibrosis of ligaments and muscles, whilst too active massage and movements in the acute stages may increase effusion into and around the joint. The two aims of treatment are described as the promotion of sound repair of the injured structures and the absorption of the traumatic effusion as rapidly as possible; chronic affections of joints and muscles are thus avoided.

The chapters on osteo-arthritis and on fibrositis are illuminating, and the comments on the successes and failures of the osteopath are of topical interest. In the sections dealing with particular joints we are especially glad to note the insistence on the importance of the recovery of full quadriceps power in knee-joint injuries; the warning against the dangers of manipulation and of all passive movements in injuries of the elbow-joint; and the description of the exact type of manipulation to be practised at the shoulder-joint, together with its contra-indication in sprain of the supraspinatus muscle. The subject matter of this volume should be familiar to every doctor, and thanks are due to the author for having presented it in such a readily accessible form and in such small compass.

The Kidney in Health and Disease

In Contributions by Eminent Authorities. Edited by HILDING BERGLUND, M.D., and GRACE MEDES, Ph.D. With the collaboration of G. CARL HUBER, M.D., WARFIELD T. LONGCOPE, M.D., and ALFRED N. RICHARDS, Ph.D., M.D. London: Henry Kimpton. 1935. Pp. 754. 45s.

THIS book is said to be an "outgrowth of a symposium on the structure and function of the kidney in health and disease which took place in Minneapolis in the summer of 1930." The principal organizer of this meeting was Dr. Hilding Berglund, at that time professor of medicine in the university of Minnesota. Of the 41 contributors 37 are American and a third of these at the time of the meeting held posts in this university; the somewhat parochial atmosphere of many of the papers may be due to this fact. The standard of the contributions is rather uneven. That the bias is on the physiological and biochemical aspects of renal research is suggested by the title, but other and more clinical topics are not neglected; of particular merit is a succinct and authoritative account of the histological changes in Bright's disease by E. T. Bell. Interesting observations and discussions of the different aspects of proteinuria, including the phenomenon of Bence-Jones proteinuria, and of œdema, with an account of the technique and effects of plasmaphæresis, will also be found. The uses of renal function tests are fully described. W. L. Longcope, J. Bordley, and F. D. W. Lukens adduce further evidence of the important part played by hæmolytic streptococci in Bright's disease. On the clinical side a description of the retinal changes in nephritis and hypertension by H. P. Wagener is supplemented by an illuminating discussion of points in their pathology by J. S. Friedenwald.

F. Volhard contributes articles on hypertension, including both pale and red varieties, uræmia, and the treatment of acute diffuse glomerulitis. Few histologists would hesitate to challenge his statement (p. 249) that "the histological picture of kidney insufficiency, whether produced through subacute or severe chronic nephritis, through malignant sclerosis or amyloid disease, or through drastic reduction of healthy renal tissue, is always the same: an astonishing dilatation of the remaining tubules and a high-grade flattening of their epithelial cells. One can see at once from a kidney section whether the patient died from renal insufficiency or not." The morbid histology is unfortunately not as simple as that, and it is a pity that so renowned an authority on renal disease should utter such a misleading statement. There seems still to be a gulf between the exponents of the clinical and the pathological aspects of nephritis, which will have to be bridged before a symposium such as this is much good to the student. Senior workers, however, will find stimulating material in its pages, making it worth their while to read it.

Eden and Lockyer's Gynæcology

For Students and Practitioners. Fourth edition by H. BECKWITH WHITEHOUSE, M.B., F.R.C.S. Eng., F.C.O.G., Professor of Midwifery and Diseases of Women, University of Birmingham. London: J. and A. Churchill Ltd. 1935. Pp. 964. 38s.

Eden and Lockyer's "Gynæcology" has been generally regarded as one of the best standard medical text-books ever produced in this country. Prof. Beckwith Whitehouse states that for this reason he approached the task of the complete revision of the work for its fourth edition with some misgivings. It is due to him that we should record the opinion, which will certainly be shared by those who study the outcome of his efforts, that he has succeeded in maintaining the high standard previously set. The advances made during recent years in gynæcology have necessitated the addition of new subject matter and the rewriting of several sections. The chapters dealing with the physiology and pathology of menstruation contain a balanced account of the knowledge at present available upon this intricate problem. The sections concerned with diseases of the ovaries have also been largely re-cast, with the introduction of new material under the title of Morbid Conditions of the Graafian Follicle and Corpus Luteum. Forty pages in Section 4 are allocated to the diagnosis of disease of the female pelvic organs. The latter part of the book is devoted to the operative side of treatment, and the description of each operation is preceded by a clear exposition of the indications for its performance. The careful account of post-operative treatment is invaluable.

We can offer no criticisms of any constructive value. The trouble expended by the publishers over the reproduction of the 600 illustrations, of which 36 are coloured, is the subject of well-deserved acknowledgment by the author.

Clinical Aspects of Visceral Neurology

By W. K. LIVINGSTON, M.D., Clinical Associate in Surgery, University of Oregon Medical School. London: Baillière, Tindall and Cox. 1935. Pp. 254. 22*s.* 6*d.*

THE author states in the preface to this volume that he intends to set forth his observations on the pre- and post-operative condition of 300 patients who have been treated by excision of some part of their sympathetic nervous system. Seeing that his experience has extended over a period of ten years we might expect the book to provide just that information which is most needed by those interested in the problems of visceral neurology. Any such expectation, however, is doomed to disappointment, for Dr. Livingston has occupied too much of his space in repeating well-known anatomical and physiological facts, and he has set down no clear statement of the results of his own operations. As a review of the more recent literature of the surgery of the sympathetic system the book is of real value, but a surgeon with Dr. Livingston's experience ought to add to our knowledge more than can be obtained from a bibliography.

The book refers to all the conditions for which sympathectomy has been performed, some of the references being of necessity brief, but special stress has been laid upon the surgical treatment of vascular diseases. The author's opinion, "there is no dividing line between Raynaud's disease and the Raynaud-like phenomena observed in the other clinical conditions such as thrombo-angiitis *obliterans*," is borne out by his records, for of 7 cases he quotes as examples of Raynaud's disease only 2 conform to the commonly accepted criteria. This unusual point of view vitiates any arguments which he brings forward regarding the nature of these vascular disorders. The number of charts of skin temperature tests bears witness to the importance of this method of investigation, but it is strange that so little is said about the effect of cooling the limbs to be tested; and since 17 out of the 22 tests used as illustrations were carried out at room temperatures of over 20° C., and in some cases at a temperature of nearly 30° C., it is unlikely that the results of these tests are at all comparable with those performed under more carefully controlled conditions. It is also remarkable that with such a wealth of available material there should have been included as an example of the effect of spinal anæsthesia the chart of a case in which the spinal anæsthetic failed to act. The chapter on surgical technique includes some useful practica suggestions, but a study of the book as a whole leave one with the impression that an authoritativ evaluation of the late results of sympathectom has yet to be made.

Forensic Medicine

By DOUGLAS KERR, M.D., F.R.C.P.E., Lecture on Forensic Medicine in the School of Medicin of the Royal Colleges, *Edinburgh.* London A. and C. Black Ltd. 1935. Pp. 311. 15*s.*

Dr. Douglas Kerr does not put this book forwar as an exhaustive work of reference. It is writte for medical students, but also contains guidanc for the practitioner. As police surgeon and medica referee to the city of Edinburgh he has wide experience, and he has been able to include from his ow medico-legal practice several striking photographi illustrations. Expressed with the clarity which on associates with good lecturing, his chapters o professional ethics and on the relation of crime an insanity are excellent. The information on toxicolog and on such special matters as blood-groups is se out in brief but comprehensive fashion. The Scottis legal procedure is as fully dealt with as the English. Such criticisms as we would offer are all trivial. It might, for instance, have been stated on p. 124 that for England the important Section 12 of the Children Act (on neglect) has been replaced by Section 1 of the Act of 1933. A like amplification is wanted on p. 188 where the 1932 enactment has been replaced as respects England by Sections 50 and 53 of the later statute. A careful study of Dr. Kerr's competent pages, doubtless destined to grow more voluminous in future editions, will enable readers to face cross-examination with confidence either in the examination room or in the witness-box in a court of law.

Lungentuberculose und Schwangerschaft

By H. BRAEUNING, Chefarzt der *Fürsorgestelle* für Lungenkranke in Stettin. Leipzig: Georg Thieme. 1935. Pp. 275. M. 24.

THAT pregnancy is capable of lighting up a latent tuberculous lesion and aggravating an active one has long been an accepted view; Dr. Braeuning's investigations have been directed towards the more exact measurement of these risks in the various types and stages of the disease. He concludes that during and after pregnancy severe and fatal relapse occurs in about 6 per cent. of cases, transitory aggravation in 20 per cent. As relapse is frequent quite apart from pregnancy these recurrencies must not be attributed entirely to pregnancy. In 102 cases of therapeutic or spontaneous abortion there was only one fatal relapse and three temporary setbacks. Relapse associated with pregnancy was found to be rather less common in fibrotic forms of the disease than it was in the exudative; but this again corresponds to experience in non-pregnant cases and it is therefore not justifiable to conclude that pregnancy has a particularly unfavourable influence on the exudative type of disease.

Twenty-four completed pregnancies in 22 women with cavities were followed by three severe and five transitory relapses. In advanced tuberculosis the prognosis is already so bad that pregnancy does not appear to shorten life; death before the end of the pregnancy is uncommon even when the disease is severe at its commencement. An unsuccessful attempt was made to forecast the likelihood of relapse by means of the sedimentation test at the beginning of pregnancy.

Br. Braeuning finds little correlation between the direction in which the disease is progressing when the pregnancy starts and the probability of relapse. He cites several cases of women who, although going downhill when they became pregnant, steadily improved during and after pregnancy;. others making good progress before becoming pregnant, suffered severe relapse, usually after delivery. Neither the original severity of the disease nor a tuberculous family history appear to have any influence on the likelihood of relapse.

The mortality during the first five years of life of children born from tuberculous mothers was found to be only 1 to 4 per cent. higher than the average. These figures are in striking contrast with the high mortality figures usually cited for untreated children by the advocates of B C G. The author actually finds no increase in infant mortality when the mother is suffering from open tuberculosis; a fact which he attributes to the great care which this group receives from the public health authorities. The main conclusion which may be drawn from this important investigation is a negative one. Modern research has failed to make more precise the knowledge that the strain of pregnancy in tuberculous women increases the risk of relapse.

Beesley and Johnston's Manual of Surgical Anatomy

Fourth edition. Revised by JOHN BRUCE, M.B., F.R.C.S.E., Tutor in Clinical Surgery, Royal Infirmary, Edinburgh; and ROBERT WALMSLEY, M.B., Ch.B., University Assistant and Demonstrator of Anatomy, Edinburgh University. London: Humphrey Milford, Oxford University Press. 1935. Pp. 717. 20s.

THE original authors of this well-known work being no longer able to cope with the responsibilities associated with the issue of a new edition, Mr. John Bruce and Mr. Robert Walmsley have taken up the burden of revision and reconstruction. They have produced a very good book, decidedly larger than in the last edition, which will meet the requirements of the present-day student. The anatomy is sound, and applied with judgment except in a few places. For example, even if one admits the possibility of the separation of the upper humeral epiphysis, it seems likely that the muscles inserted into the epiphysis have more to do with the injury than has the capsule. There is an excellent general account of the autonomic system. The writers have resisted the temptation to introduce such experimental details as frequently confuse and irritate the reader, and have produced a clear and eminently understandable account of the matter. The commoner surgical procedures which have to do with this system are shortly but well described from the anatomical side, but the few lines which deal with removal of the right lumbar trunk might be improved by some mention of the presence of the vena cava and ureter. In a future edition, some of the developmental data given throughout the book should be revised. The work seems to meet well the purpose expressed in the preface, the provision of a manual for use by senior students in the dissecting room; for such a purpose it can be heartily commended. It is well produced and clearly, if not too profusely, illustrated.

Electrokinetic Phenomena

And their Application to Biology and Medicine. By HAROLD A. ABRAMSON, M.D. American Chemical Society Monograph Series. No. 66. New York: Chemical Catalog Company, Inc.; London: Arthur F. Bird. 1934. Pp. 331. 33s. 6d.

THE American Chemical Society Monograph Series contains some most valuable works of reference to isolated chemical problems, and this volume will add to its reputation. In the space of some three hundred pages Dr. Abramson has provided a clear and comprehensive account of the application of physical methods, such as electrodialysis to biological and medical problems. The first chapter is concerned with historical development. Starting with an excellent photograph of Smoluchowski the author traces the development of the study of electrochemistry and gives in considerable detail the earlier work of Reuss, who, as he points out, was the true discoverer of electro-osmosis The way in which Dr. Abramson leads up to the conception of the electric double layer and its bearing on physico-chemical phenomena deserves special praise. The text is attractively illustrated by reproductions of the early apparatus. Later chapters deal first with the theoretical aspects of the subject and then with its practical applications to various problems of biochemistry and bacteriology. The summary of the literature is judicious and contains a useful section on the patent literature.

The Theory of Gymnastics

By Prof. JOHANNES LINDHARD, M.D., Professor of Gymnastic Physiology, Laboratorium, University of Copenhagen; Principal of State Institute of Gymnastics, Copenhagen. London: Methuen and Co. 1934. Pp. 359. 12s. 6d.

THIS is a serious analysis of gymnastics, which will be found stimulating by those interested in the various schools of physical education and in the applied theory of movement. Prof. Lindhard is somewhat antagonistic to the accepted Swedish Ling school of gymnastics. Many of his contentions, we feel, could be countered by a more understanding knowledge of the views of the best thinkers and not the average workers of this school. He discusses, in an original way, the development of gymnastics and its modifications. His critical allusions to modern system modifications, as those of Bukh, Björksten, Knudsen and Elin Falk, are not unjust. He deals at length with the various classifications of exercises, and comments on the aim and application of gymnastics as evinced by these groupings of movements. He has little use for the orthodox conception of the fundamental standing position, which in his view compares unfavourably with the classical Greek form, and he analyses the "attention" position of any system as its keynote.

Prof. Lindhard lays emphasis, illustrated by detailed anatomical facts, on the differences between the sexes, and on the desirability of different movements for men and women. This thesis he seems to pursue too far in proclaiming an arbitrary taboo on certain movements for women on æsthetic grounds. The idea that the gymnast is endeavouring to straighten the natural curves of the spine beyond Nature's intention rouses Prof. Lindhard to a brisk attack. This zeal might be modified by the consideration that the whole of civilised daily life tends to increase these curves, and the idea behind any but the most unintelligently military system is simply a return to normal. His analysis of breathing exercises, however, provides a fresh and stimulating outlook, and his comments on the association of respiration with heart function are original and suggestive. The section on marching is also of practical interest. Throughout the book Prof. Lindhard appears to be reacting against a hypothetical antagonist; those who uphold traditional methods of gymnastics would probably agree with many of his criticisms, and would yet find adequate reasons for adapting rather than scrapping the orthodox routine.

Medicine in Persia

By CYRIL ELGOOD, M.D., M.R.C.P. Clio Medica Series. New York: Paul Hoeber. 1934. Pp. 105. $1.50.

THE attitude of the Persians to medicine seems to have been chiefly receptive, the teaching of their own Zoroaster having been modified by Egyptian, Mesopotamian, and especially by Greek influences. Successive political changes, and no doubt the artistic langour of the East, prevented their producing more than three great physicians—Rhazes, Avicenna, and Ismail. Of these, Rhazes (A.D. 850–932) is the best known for his differentiation of both measles and small-pox, but he also introduced mercury ointment, and discovered sulphuric acid amongst other things. Avicenna (A.D. 980–1037) was renowned for his celebrated "canon," founded largely on Galen and received with joy by European physicians in the sixteenth century. Ismail, who died in A.D. 1136, described exophthalmos as an accompaniment of goitre and was thus, as Dr. Elgood points out, the first to observe a sign rediscovered by Dr. Parry in 1825. On the whole the treatment of physicians by Persian monarchs appears to have been good, and it is clear from Dr. Elgood's learned and instructive work that hospitals and medical schools flourished in Persia and Bagdad long before they were founded in European countries. According to Dr. Elgood, the medicine of the New Testament shows evidence of the influence of Persian medicine, and the term Magus is the old Persian name for a Zoroastrian priest.

L'épaule

Anatomie des Formes Extérieures, Anatomie Radiographique, Chirurgie Opératoire. By ANTOINE BASSET, Professeur agrégé à la Faculté de Paris, Chirurgien de l'Hôpital Beaujon; and JACQUES MIALERET, Aide d'Anatomie à la Faculté. Paris: Masson et Cie. 1934. Pp. 292. Fr.65.

THE authors have now produced two volumes in their series dealing with the topographical anatomy and surgery of the large joints. That dealing with the knee-joint has already been reviewed in these columns; the volume on the ankle-joint is being prepared. The complete series will undoubtedly be an asset to any surgical library. The standard set by the first volume was high, and it has been well maintained. The general scheme followed here is for the most part the same as in the account of the knee-joint. The first and smaller part of the work is devoted to anatomical descriptions, including surface anatomy and radiographical appearances, both of the normal joint and of joints specially prepared by injections of the capsule and arteries. Reconstructions of the muscle relationships have been produced by drawing the muscles over radiograms. Anatomical points of surgical importance are noted. This part of the book is profusely and finely illustrated; the illustrations, indeed, are descriptions in themselves.

Operative surgery is dealt with in the second part. The authors seem to have been at pains to include every operation and every incision that can possibly be used to expose the shoulder-joint. This mass of information tends to bring confusion in its wake, even though a résumé is given at the end of the chapter on incisional approach by the five routes which are considered to be of value. In the section on injury the indications for operation are clearly presented. Three principles are laid down: (1) in all injuries in the region of a joint it is essential to make sure whether the joint itself is or is not involved; (2) in all non-infected articular injuries closure without drainage is to be performed; and (3) all infected injuries of joints are to be treated by free drainage. Exploration by open incision, dividing layer by layer, of any wound suspected of opening into the joint is recommended. The futility and danger of exploring by a probe is emphasised. Dislocation of the shoulder is discussed at length in as far as the injury may require open operation.

The consideration here devoted to the after-results of the various surgical procedures will be welcomed.

Anatomy: The Thorax

Fourth edition. Part V. (Catechism Series). By C. R. WHITTAKER, F.R.C.S.E., F.R.S.E., Lecturer on Anatomy, Surgeons' Hall, Edinburgh. Edinburgh: E. and S. Livingstone. 1935. Pp. 59. 1*s.* 6*d.*

THIS well-known series certainly helps those students to whom all the institutes of medicine (as well as that art itself) are simply exercises for their memories and hardly at all for their reasons. For these, books of this kind can be recommended, not as treatment of the condition but to relieve or hide the symptom. This little book is full of accurate information, from cover to cover, but that is not to say that it can teach thoracic anatomy to those who will not use their faculties properly. On the other hand, it may help those who have some knowledge of the subject to get their information in order.

REPORTS AND ANALYSES

MOUSSEC

(MOUSSEC LTD., 175–6, PICCADILLY, W.1)

THIS is a sparkling wine of the champagne type prepared from imported grape must and fermented in this country by suitable selected champagne yeasts. The treatment of the wine during and after fermentation is the same as carried out in the well-known wine houses in France. When analysed the following results were obtained:—

Alcohol (by volume)	12·0	per cent.
Equivalent to proof spirit	20·65	,,
Total extractives	3·93	,,
Consisting of—		
Invert sugar	1·97	,,
Cane sugar	0·29	,,
Fixed acidity (as tartaric acid)	0·51	,,
Mineral matter, &c.	1·16	,,
Volatile acidity (as acetic acid)	0·06	,,

The wine has the appearance, composition, and general properties of an ordinary dry French champagne. It is light and pleasant to the palate, and has an agreeable aroma. The manufacturers would seem to have succeeded in making, in this country, an attractive and wholesome wine closely resembling the imported product.

THE LANCET

LONDON: SATURDAY, JULY 6, 1935

THE INFLUENZA VIRUS IN RELATION TO PROPHYLAXIS AND TREATMENT

If there are any who are still truly in doubt whether the prime cause of epidemic influenza is a filtrable virus, let them read the Linacre lecture delivered recently by Sir Patrick Laidlaw, F.R.S.[1] They will find there set out with admirable clearness the evidence which Laidlaw and his colleagues, C. H. Andrewes and Wilson Smith, have produced in support of the virus hypothesis. It is a record of brilliant work which makes a most convincing story, the more so because of the restraint with which it is told, and because of the scrupulous care with which each fact has been weighed and examined before being accepted.

The history of the virus hypothesis of the cause of influenza falls naturally into two periods. Prior to 1933 the only available experimental animal was man, on whom the hypothesis could not be adequately tested, and though evidence had been obtained in support of the virus theory, it fell far short of convincing proof. In 1933 came the important announcement in our columns by Smith, Andrewes, and Laidlaw[2] that the ferret was susceptible to influenza. A new era in influenza research was inaugurated and the march of events has been rapid. The demonstration in 1933 that a filtrable virus is present in the nasopharynx of early cases of epidemic influenza and that specific antibodies can be demonstrated in the blood of human and ferret convalescents was soon followed by the discovery that the mouse is susceptible to the influenza virus and that it is possible to prepare a specific antiserum in the horse.[3] The group of workers at Hampstead were now in a position to isolate and type viruses from subsequent cases of influenza. The year 1934 proved disappointing inasmuch as there was no widespread epidemic of influenza in London from which to obtain material, but the one strain isolated was shown to be identical with the 1933 strain. In the winter of 1934–35 eight new strains were obtained, six from an outbreak in Shorncliffe and two from the London area; these again, though not yet completely investigated, seem to be identical with those previously isolated. Added to this comes evidence from America where Dr. T. Francis, Jun., working at the Rockefeller Institute, has isolated two strains of influenza virus, one from an outbreak at Porto Rico and one from Philadelphia in 1935. Both these strains are neutralised by the specific antiserum made at Hampstead by the British workers, so that it would appear that epidemic influenza is produced by one and the same virus in different parts of the world. The virus hypothesis, to quote Laidlaw's words, is "already transformed into a theorem."

What is the practical significance of this? The clinical observation that one attack of influenza in man does not leave a lasting immunity, and the lack of success which has attended attempts at serum *therapy* in virus infections might well suggest that these discoveries while of immense scientific interest may be of little material value in the control or treatment of epidemic influenza. That such a hasty conclusion would be quite unjustified at this stage is clear from the two new papers dealing with immunological problems of experimental influenza just published by the Hampstead team.[4] [5] The ferret, they find, as the result of recovery from infection with influenza virus, becomes immune to reinfection; specific antibody is present in its blood. But after an interval of a few months this immunity wanes, the antibody titre falls, and the animal becomes susceptible to reinfection. It is important to note that the ferret becomes susceptible again despite the presence of some circulating antibody, and that its immunity can be restored by the inoculation of virus subcutaneously, a non-infective route. Now random sampling of human sera has shown that the very great majority contain antibody for the virus, presumably as the result of previous infection, and it seems just possible that, as in the ferret, the immunity possessed by humans could be reinforced by prophylactic inoculation. In this way it might be possible to tide individuals over the period of epidemics of influenza. Another point of importance which emerges from these recent studies of influenzal immunity is that the antiserum made in the horse seems to possess some therapeutic value when tested in the mouse. When serum is given along with virus, infection can be prevented; that was to be expected. But the astonishing thing is that even when given 48 hours after infection, this serum exerted a quite definite effect on the course of infection, as was evidenced by the reduced mortality-rate. In one experiment serum given even three days after infection had an appreciable effect. The authors are naturally chary in forecasting the value of this serum used therapeutically in man, but the prospect that a serum of such a high potency may be of use in the treatment of influenzal pneumonia seems sufficiently likely to make its clinical trial an exciting adventure.

THE SINGER'S NODULE

The little nodule which makes its appearance on the vocal cord is never a danger to life or health, but is of serious importance to professional voice-users whose means of livelihood it may destroy for a prolonged period or even permanently. In England it is usually called the "singer's nodule," though it is at least as liable to occur on the cords of other voice-users, such as school-teachers; among singers it is commoner in sopranos and tenors than in alto or bass voices, and it is fairly frequent in young children. It may be unilateral or bilateral, and is situated on that part of the vocal cord which is the "seat of election" for this and other small innocent growths. This seat of election is variously stated by different authorities to be at the junction of the anterior and middle thirds of the vocal cord, or at the middle of the cord, which position corresponds to the junction of the anterior and middle thirds of the glottis, the hinder third of the glottis being bounded by the arytenoid cartilages. Dr. Jean Tarneaud in an informative and erudite study of this node and its manifestation[1] gives the former, but his diagrams appear rather to favour the latter situation.

It is common ground among laryngologists that these nodules are the result of abuse or faulty production of the voice, and of the nature of a corn due to local attrition; but the exact mechanism of their causation has never been satisfactorily explained. The principal object of Dr. Tarneaud's monograph is to supply the deficiency, which it does in a precise and ingenious manner. Some laryngologists believe that inflammatory swelling of the cords, by bringing their centres into contact during phonation, is the cause of irritation at this spot, but Dr. Tarneaud denies that inflammation plays any part, or that any sign of inflammation is ordinarily apparent. Inflammatory paresis of the thyro-arytenoid muscles is classically represented by an oval glottis with separation of the cords. Neither is the site of the nodule the place of maximum vibration, for he finds on examination with the stroboscope that the cords vibrate equally throughout their length. The little globule of mucus, which is sometimes seen to collect on the seat of election during phonation, would not remain on the place of maximum vibration. The existence and situation of this globule is important for the author's argument; he believes that it forms where it does because this place has pathologically become the lowest point of the cord. According to him the essential cause is a myopathic paresis of the tensors and adductors; the former causes a downward sagging of the cords, while the latter produces an eversion whereby the lowest point is directed inwards and so approaches the corresponding point of the opposite cord. It is an ingenious hypothesis, arrived at by much thought and painstaking observation, and not lightly to be dismissed. In treatment, Dr. Tarneaud favours surgical removal of the nodule, and treats perhaps rather lightly the danger of damage to the cord even by experienced laryngologists; he rightly insists on the paramount importance of vocal re-education in the after-treatment, and is convinced that good results cannot be obtained by silence without re-education. He does not deny that cures have been obtained by vocal rest, but believes that they are rare, and he emphasises the bad moral effect of prolonged silence on the professional singer.

PHARMACEUTICAL STERILISATION

There has of late years been an immense increase in the quantity and variety of remedies administered by some form of injection, and the question of how the solutions used should be sterilised has thus assumed considerable importance. To ensure complete sterility means nothing short of autoclaving; many dispensing chemists do not possess autoclaves, and no one knows whether certain drugs are sufficiently thermostable to resist this process. Filtration is another process employed by the more enterprising, but this itself demands the possession of an autoclave in order to sterilise the filters; it is subject also to doubts connected with the possible adsorption of active ingredients in a solution by the filter itself. It has been a common practice to attempt sterilisation by discontinuous heating (Tyndallisation), the assumption being that spores will be transformed into vegetative bacteria during the intervals between heatings and so become vulnerable to moderate heat. This process serves well for culture media, as it did for Tyndall's hay infusions in 1881, because a nutritive environment encourages multiplication; but there is nothing in most solutions of drugs to beguile a spore into a misguided attempt to grow, and it is consequently not surprising that H. Davis[1] found discontinuous heating to 80° C. incapable of sterilising solutions containing spores. He described to the British Pharmaceutical Conference held last week in Belfast several further series of experiments with a bearing on this matter, which are published in the special number of the *Quarterly Journal of Pharmacy and Pharmacology* devoted to the proceedings of this conference. In the first place it would appear that if solutions are made with precautions against contamination they will often be sterile from the beginning, since he has shown that many drugs in the solid form are free from bacteria, or form solutions which are actually bactericidal (for *Staphylococcus aureus*). The former findings must be accepted with reserve, because the quantity cultivated is not specified, and the absence of growth may have been due simply to inhibition by the drug itself. The temperature of incubation is also not mentioned; it was presumably 37° C., and quite different results, though possibly of less importance to the safety of the patient, might have been obtained at a lower temperature. It has to be remembered that solutions which originally were sterile may become contaminated during repeated use, and this fact introduces the question of preservatives—another matter in which finality has by no means been reached, since no known preservative has ideal qualities, and some have known or may have unknown effects on the solutions in which they are used. Davis has tested a number of these, with disappointing results in the case of chlorbutol and certain *p*-hydroxybenzoic esters which have recently found favour on the continent, and highly favourable results for merthiolate and *para*-chloro-*meta*-cresol. The only test organism used was *Staphylococcus aureus*; other bacteria and moulds might well have been found to be much more resistant.

[1] Quart. Jour. Pharmacy and Pharmacol., 1934, vii., 379.

Incomplete as this information is, it serves to explain a good deal of past experience, and may afford useful preliminary indications to anyone inclined to pursue the matter further. The fact is that ordinary cleanliness and simple boiling will obviate all but very remote risks; to remove that final residuum of danger there is no alternative to autoclaving or filtration, and one of these processes should certainly be applied to such materials as calcium chloride solutions, and solutions capable of supporting bacterial growth or used for such purposes as retrograde pyelography or injection into any other vital and vulnerable tissues. Hypodermic and intravenous medication, in spite of the frequent use of contaminated solutions, is generally safe either because the bacteria concerned are non-pathogenic or because the connective tissues and the blood are capable of disposing of them.

VARIOUS KINDS OF MILK

FEW people understand the meaning of the titles under which milk is now sold in this country, and it is satisfactory to hear that a less complex terminology is under consideration by the Ministry of Health. So far as the proposals are available the chief differences lie in the discontinuance of the present "Certified" grade; the use of the term "Certified" for milk produced under almost the same conditions as the present Grade A (T.T.) (the latter name being abandoned); and the abolition of "Grade A" in favour of a new designation "Standard," this name, however, being applied for wholesale purposes only. The simplification of nomenclature is all to the good. The new Certified milk comes from herds freed from tuberculosis and will be produced according to a fair standard of cleanliness, not more than 200,000 bacteria being present in each cubic centimetre at any time before delivery to the consumer. Such milk is almost safe as regards risk from tuberculosis, but it may of course contain *Brucella abortus* and other organisms; for example, E. J. PULLINGER,[1] examining 101 samples from 45 tuberculin-tested herds found tubercle bacilli in 1 and *Br. abortus* in no less than 70. Accordingly, for the benefit of those who demand precautions beyond tuberculin-testing and cleanliness, permission will now be granted to pasteurise Certified milk. So much for the highest grade: now we turn to the new Standard milk, on which interest will largely centre. The demise of Grade A, with its unwarranted implication of high quality, will certainly not be lamented, but it has to be noted that the requirements for Standard milk are even lower. This grade, as already stated, will not be sold as such to the public, and apparently it is defined purely in order to enable its producers to qualify for the roll of "accredited producers" under the Milk Marketing Board. The cows are not to be tested with tuberculin and the quarterly veterinary inspection they will undergo is an insufficient precaution against excretion of tubercle bacilli in the milk—apart from other risks. The requirements for production are below those for Grade A, and instead of a definite bacteriological standard a simple colour test is proposed. The details of this proposal are not yet forthcoming, but it is generally held that all the published colour tests (such as the methylene-blue reduction-time) are variable in their indications and too lenient for use in obtaining a reasonable level of cleanliness. Standard milk, like accredited milk as originally proposed, will be somewhat cleaner than ordinary market milk, but very little safer. It cannot be recommended by the medical profession as safe for consumption in the raw state and it will therefore need pasteurisation.

In the new Order pasteurised milk is to be defined very much as at present, with some small improvements. The bacterial count is to be not more than 100,000 per c.cm. at any time before delivery to the consumer; on the other hand no standard is laid down for testing the efficiency of pasteurisation and the difficulty remains that bacteria may be added in the cooler and the bottles and by multiplication after heating. Hitherto no convenient test for adequate pasteurisation has been available: the presence of tubercle bacilli can be ascertained by inoculation into guinea-pigs, but this is not a method suitable for routine testing of the efficiency of commercial plants. In these circumstances close attention should be paid to the paper by Prof. H. D. KAY and Mr. F. K. NEAVE in our last issue describing a phosphatase test and illustrating its practical utility. Phosphatase in milk, it appears, has the happy characteristic that it is destroyed at almost the same time-temperature combination as the official requirement for pasteurisation, and the presence or absence of this ferment in milk is therefore a guide to the efficacy of the heating process. KAY and NEAVE's investigation suggests that much of the pasteurised milk they examined had been heated insufficiently, and if their test is accurate it shows a large number of pasteurising plants of all sizes both in London and elsewhere are functionally inefficient or unsatisfactorily operated. This conclusion, however, comes as no surprise, and the explanation is not far to seek. Supervision of pasteurising plant is a definitely technical task, but in practice it is in the hands of sanitary inspectors with very wide duties, few of whom really understand the criteria either for licensing or operation. Much more elaborate instruction is needed for those charged with this responsible work,[2] and it seems decidedly unfortunate that in the proposed Order, while Certified and Standard milk are to be supervised by county and county borough councils, the licences for pasteurised milk are still to be issued by the local sanitary authorities.

---

[1] THE LANCET, 1931, i., 967.

[2] *Vide* Sir W. Dalrymple-Champneys's report on the supervision of pasteurising plants. Min. of Health Rep. on Pub. Health and Med. Subjects No. 77. 1935. Reviewed in THE LANCET of May 18th, p. 1152.

This means that in the counties responsibility for these plants will be in the hands of a large number of rural sanitary inspectors without any special experience of the essential requirements; whereas under county councils it would be practicable to put all this work in the hands of a single officer who could be given the necessary training.

Talk about milk and its designations is interminable, and there must be many medical men who feel that it bears little relation to their own work. But statements such as those made by Dr. VEITCH CLARK, medical officer of health for Manchester, in the paper reported on p. 38, are really a challenge to the profession and the community as a whole. It is intolerable, he said, that we should put up with the sale of a food known to be producing an enormous bulk of disease, and he recommended pasteurisation as the principal solution of the immediate problem. Properly performed, this process will kill tubercle bacilli and *Br. abortus*, as a further paper by Mr. PULLINGER in our issue of June 8th once more illustrates. And there is no reason why it should not be properly performed if we will only insist on a high standard of equipment, supervision, and laboratory control.

ANNOTATIONS

CHRONIC RHEUMATIC DISEASES

THE British Committee on Chronic Rheumatic Diseases, already in existence under another title, was officially adopted by the College of Physicians early in 1934, for the purpose of stimulating professional interest in rheumatoid arthritis and related conditions, and encouraging the investigation of them. The committee now presents its first report,[1] a handsome volume of 170 pages. Sir Humphry Rolleston, the chairman, opens it with a foreword, which, like an operatic overture sketches the themes that are to follow. Dr. W. S. C. Copeman, the secretary, records briefly the history of the committee, which is clearly no perfunctory body, but a group of active and responsible people who feel that the profession is doing less than it ought to grapple with a common and cruel disease. Then comes a series of papers, some by members of the committee and some by others associated with it, which indicate the attitude of British medicine to the major problems of chronic rheumatism, and the lines along which some current investigations are proceeding. The first of these is the report of the nomenclature subcommittee, offering as basis for a working classification the familiar headings "rheumatoid" and "osteo-," but applying these to types of joint change, not to actual diseases. The rheumatoid type includes gonococcal and other specific arthritides, alongside Still's disease, classical rheumatoid arthritis, and climacteric villous arthritis; the osteo-arthritic type embraces some gouty joints, and Charcot's joints, as well as osteo-arthritis of traumatic and of unknown ætiology. The justification for this lies in the morbid anatomy, which is set forth in a dozen pages of excellent description.

Among the contributors Dr. John Freeman sketching the present position of allergy and hypersensitiveness in chronic rheumatism and arthritis, looks with a properly critical eye, and paints with a lively brush. "Allergy" is for him so difficult to define, so vague and variable in its uses, that he finds it more hindrance than help; he suggests indeed that the euphony of the word is more responsible for its popularity than any idea lying behind it. In the fog that covers the bacteriological aspect of chronic rheumatism he feels sure of only one thing—that infection, or more likely infections of many kinds, are essential to its causation; how and why the joint changes result from the interaction of host and micro-organism is quite obscure. Mr. Joseph Race summarises the biochemist's contributions to the subject, and gives a good account of the blood sedimentation-rate; accelerated sedimentation is due to altered proportions or properties of the plasma proteins, which, he wisely says, are greatly in need of some more investigation. Dr. C. W. Buckley, the editor, writes a valuable little clinical account of ankylosing spondylitis, based on 150 cases in his own practice. After several shorter papers of less importance come four critical commentaries, by members of the committee, in which sections of the recent literature are surveyed and discussed: Mr. Timbrell Fisher deals with pathological and orthopædic work, Dr. G. H. Oriel with the general trend of research in 1934, Dr. Buckley with neurological manifestations of vertebral rheumatism, and Dr. Francis Bach with the thyroid and parathyroids. Finally there is a bibliography of chronic rheumatism in the medical literature of the last twelve months.

We have described the contents of the report in this detail because it deserves wide attention. The idea of clinical research by means of a sort of royal commission may not at first glance seem promising, but in this disease, of which we are nearly all weary through familiarity, the first need is to awaken a brisk interest, perhaps even to spur a complacent conscience. The second is to set the problem in some sort of perspective, indicating what knowledge has so far been won, what generalisations are most likely to hold good, and warning against will-o'-the-wisp theories and catchwords that have no meaning. Both those needs are faced in this first report, and the form in which it is cast—individual contributions instead of a formal report under headings—gives it an added appeal. Except for the secretary's paper on histamine, it says little about treatment; that is to come later. In some places the views of its contributors are open to criticism, but in the main it is informed with a sober enthusiasm. It should be read by all who feel any responsibility towards the teaching or the advancement of medicine, and it should help to convert all chronic arthritics in hospital beds and out-patient departments into "interesting cases."

DUODENAL EXTRACT IN DIABETES MELLITUS

SINCE the discovery of insulin there has been much speculation as to whether it is the only substance found in the body which influences the sugar metabolism. A substance having an insulin-like action has been isolated from the mucosa of the stomach and of the duodenum.[1] [2] Macallum believes that an insulin hormone is produced in the duodenum when sugar enters the intestines.[3] With Laughton and others[4] he studied the effect of a duodenal extract on dogs and rabbits; they found that it has no effect on a normal or a completely depancreatised dog, but that the partially depancreatised dogs were benefited when the substance was either injected subcutaneously or given by mouth. Duncan, Shumway, Williams, and Fetter[5] have now treated 30 diabetics with this extract. They took patients with mild and severe types of the disease and gave the extracts by mouth either when the patients were passing sugar or when insulin was discontinued having previously been given. Sugar-tolerance curves were performed at intervals on the milder cases. The authors conclude that the extract is of no value in reducing a distinct hyperglycæmia and has no effect when given with insulin. An effect, however, is discernible if both insulin and extract are given together for some days, and the insulin is then suddenly discontinued; if the extract had no value the glycosuria would reappear at once under these conditions, but it does not do so. A dose of 0·25 g. three times a day had as much effect as bigger doses. If the sugar tolerance is then tested, a normal curve may be obtained and this good result may persist for some weeks. The series treated included 12 cases of severe diabetes of which 8 showed a definite response, while 4 were unaffected; of 18 mild cases treated 11 were benefited while 7 did not improve. The inconstancy of these results is difficult to explain. Experiments in the treatment of diabetics are, however, always complicated by the capacity of both severe and mild cases to improve very considerably without any obvious cause. The results obtained by Duncan and his collaborators are thus by no means conclusive and can certainly not be accepted as proof of the presence of a special substance in the duodenum which is of value in the treatment of diabetes.

MEDICAL EVIDENCE OF DRUNKENNESS

AT its last meeting on June 27th the Medico-Legal Society discussed the subject of drunkenness in the courts. Comprehensive papers were given by Mr. Everard Dickson, a metropolitan magistrate, and Dr. Gerald Slot respectively on the legal and the medical side of drunkenness. The subsequent discussion naturally centred round the vexed question of proving the drunkenness of a motorist who is charged under the Road Traffic Act 1930 with being under the influence of drink to such an extent as to be unable to exercise proper control of his car. There was general agreement that drunkenness has no one symptom which it does not share with other disorders. Dr. Slot gave some useful suggestions on differential diagnosis designed to enable police surgeons and others to distinguish between the effects of drink and those of nervous disturbance, either chronic or caused by the accident, or the effects of drugs or diabetes. The testing of the suspect motorist in the police-station is not by any means a simple matter, for though his breath may smell of alcohol, it will do this if he has taken the smallest quantity. It is possible that he may be slightly under the influence of drink but still capable of having proper control of his vehicle, and other causes may account for his appearing deeply intoxicated. It was agreed that tests which called for some unusual action, such as changing direction at the word of command, were unfair in any event, and two speakers recommended as a test for memory, orientation and ordinary common sense that the suspect should be asked to look up a number in the telephone book. Sir Bernard Spilsbury, who occupied the presidential chair for the last time, emphasised the possibility that shock might simulate intoxication; a motorist might be deeply shocked by a collision and be quite unconscious that he had suffered injury. On the legal side, as Mr. Justice Humphreys pointed out, medical tests in general carry far less weight than they would before a tribunal of medical men. Juries come to their conclusion largely on matters of fact, such as the amount of alcohol the accused had taken, the circumstances of the accident and his behaviour immediately afterwards. If conviction in a particular case depended upon the medical evidence, the jury, he said, were far more likely to give the man the benefit of the doubt. The view of the meeting appeared to be that a fairly severe degree of intoxication should be proved before the motorist was convicted, though this was not expressed in so many words by any speaker. It is rather curious that no one put forward the view, which has much authoritative support, that a very slight degree of alcoholism, not amounting to drunkenness in any sense, is capable of depriving many motorists of proper control.

THE TWO-SHIFT SYSTEM IN INDUSTRY

CLOSE on one hundred years ago a prolonged industrial battle was raging which terminated in 1847 in the Ten Hours Act—while Manchester protested that profits only came from the last two hours of the twelve-hour day. This Act limited to ten hours, between 5.30 A.M. and 8.30 P.M., the working day of protected persons—i.e., of women and anyone under 18 years of age. It was, however, so drafted that employers were able to introduce the relay system, whereby they claimed to be employing one set of protected persons the first half of the day and another in the last half. In fact, they often employed the same persons from 5.30 A.M. to 8.30 P.M.; detection was impossible because the workers colluded with the employers in giving false evidence. To meet this difficulty an amending Act was passed in 1850 limiting factory hours to between 6 A.M. and 6 P.M., or 7 A.M. and 7 P.M.; and this limitation still holds for protected labour. There never has been any limitation of factory hours for adult males, and at the moment there is not likely to be. The International Labour Conference at its nineteenth session last month had before it a general draft convention on the 40-hour week and approved it in principle. But its application depends on the adoption of separate conventions for individual industries, and it looks as if it will be long before the convention will have any practical bearing on factory hours.

As regards protected labour, a report[1] has just been issued in which an influential committee under the chairmanship of Sir Malcolm Delevingne unanimously praises the two-shift system which, since the war, has been permitted under Special Orders. It permits protected persons to be employed in two successive shifts (averaging not more than 8 hours each) between 6 A.M. and 10 P.M.; the shifts are usually 6 A.M. to 2 P.M. and 2 P.M. to 10 P.M. No substantial difficulties have arisen in enforcing compliance with the Orders made; certainly no return to breaches of the relay system has been experienced. The *two-shift system provides valuable elasticity in* the adjustment of plant to output; it enables costly machinery to be worked 16 hours a day, whereby it can be worn out before it becomes obsolete owing to new devices or changes in fashion; it permits advantage to be taken of a glut in supplies in seasonal trades, such as vegetable canning; and it does something to lessen unemployment without increasing expensive plant. In fact the more costly the plant, the more advantageous is the system. No medical evidence was forthcoming that the standard of health of shift workers was below that of day workers, or that they suffered in any way. But a suggestion is made for a fortnightly alternation of shift, since the sleep of those on the early shift tended to be curtailed, while that of those on the second shift was correspondingly lengthened. Much consideration is given in the report to evidence scientifically collected by the Industrial Health Research Board. Information obtained from the International Labour Office at Geneva indicates that other countries use the two-shift system advantageously far more than we do. The single alternative is overtime, which by common consent stands condemned, unless for some quite unforeseen rush.

[1] Report of Departmental Committee on the Employment of Women and Young Persons on the Two-shift System. 1935. London: H.M. Stationery Office. Cmd. 4914. Pp. 97. 1s. 6d.

The only objections of moment concern the disturbances to social life, due to early rising and lack of transport facilities for the early shift. Should, as is probable, the system come to be more widely used, these objections will naturally be overcome. Recommendations are made for embodying, under simplified official permission, this new shift system in the hours permitted under the Factory Acts; but, wisely, only where a high standard of service is maintained in canteens and messrooms, so that full benefit may be taken of the half hour allowed for meal time. Adoption of the recommendations will constitute an important landmark in the industrial life of this country.

THE MEDICAL ART SOCIETY

THE first annual exhibition of the Medical Art Society has now been opened; a private view took place in the Council room of the Royal Society of Medicine last Friday, June 28th. Fifty-four doctors showed their work and it was of a pleasantly varied sort. Undoubtedly the technical skill of some of the exhibitors was ahead of that possessed by others, but the impression derived from the whole display was that the general level was high and that a fair proportion of the work shown would have gained a place in shows where to paint was the professional métier. The exhibition consisted largely of paintings, *only 9 out of the 152 works being sculpture or wood*-work, and only 22 being black-and-white drawings. The rest of the exhibits were divided into 35 oil paintings and 86 water colours, and one or two of the exhibitors showed pictures in more than one class. The diversity both of aim and technique was, as might be expected, considerable, and this was equally noticeable in the oil paintings and the water colours. Several artists, not among the veterans, were more influenced by the style and aims of masters now thought to be old-fashioned, than were their elders; others who will be found among the seniors in age, appear to have turned more deliberately to modern schools for their guidance. The exhibition shows what was common knowledge, that many doctors look for relaxation in painting, and that some acquire real proficiency. The original scheme for founding the society mentioned specifically that medical illustrations would be included in its exhibition, but only one contributor to the show followed this hint. *The exhibition will remain open free of charge* until July 12th. The president of the Society, Sir Leonard Hill, and the honorary secretary, Prof. C. A. Pannett (131, Queens-road, Richmond, Surrey), are to be congratulated on the successful inauguration of an interesting movement, while particular thanks are due to Mr. Norman Sylvester, curator of the Russell-Cotes Art Gallery of Bournemouth, for his assistance.

PUBERTAS PRÆCOX

PUBERTAS præcox is a rare condition of which the ætiology is so little understood that a documented case report is of universal interest. At a meeting of the clinical section of the Royal Society of Medicine three years ago[1] Dr. H. S. Le Marquand showed a prematurely developed boy whose later clinical history with the pathological conditions found post mortem is fully set out in the Royal Berkshire Hospital Reports.[2] At his death the boy was four years and ten months old and he had been under observation from the age of two and a half years. At fourteen months the genital organs and pubic hair had begun to grow with abnormal rapidity, and from that time onwards there was a remarkable increase in height, weight, and muscular strength. Sexual symptoms appeared at one year and ten months and were excited by the presence of adult females. Mischievous and destructive in his habits, he showed a tireless activity, was abnormally strong for his age, and showed great interest in mechanical devices. When only two years old he attempted to drive the farm tractors while seated on his father's lap. He was not otherwise remarkable in intelligence or habits. Physical examination revealed nothing abnormal in the central nervous system, chest, or abdomen. Between the ages of two and three years two exploratory operations were carried out in the expectation of finding a suprarenal tumour, but none was found. Three months after the second operation it was observed for the first time that he made sexual advances to small girls, having formerly been attracted only by adults. His abnormal strength about this time is witnessed by his ability to push his father's motor cycle and side-car out of the shed on to the lawn, which he did after dark.

In May and June, 1933, when he was nearly four years old, the removal of one testis and of one suprarenal gland was carried out in two operations with a view to the alleviation of symptoms. As a result sexual activity became less marked in the succeeding months; it was also noted that the hair of his head became less coarse although, as before, it grew with remarkable rapidity. At the end of February, 1934, he developed rheumatic fever and this caused his death in the following April. Graphs of the increase in weight and height show a steady upward curve except for a slight set-back after the last two operations. Analysis also shows a relative retardation in the growth of the long bones from the thirty-first to the forty-third month, during which time development of the short bones was unabated. Radiograms at the fifty-eighth month show evidence of approaching closure of the epiphyses of the long bones so that, as Le Marquand says, "if the child had lived, a stunted dwarf, with an abnormally long upper measurement and short arms and legs, would have resulted." At necropsy the only significant lesion found by Dr. D. S. Russell was a tumour about the size of a hazel-nut firmly attached to the right corpus mammillare and the adjacent tuber cinereum and suspended in the interpeduncular space. The rest of the brain, including the pineal body, was normal. Histologically the tumour presented the appearance of normal brain tissue, with fully differentiated neurones and neuroglia and occasional bundles of myelinated fibres. The hypothalamus, examined by serial section, showed no abnormality. The only other histological observation of interest was the presence of active spermatogenesis in the testis.

[1] Proc. Roy. Soc. Med., 1932, xxv., 106.

[2] Le Marquand, H. S., and Russell, Dorothy S.: Roy. Berks. Hosp. Rep., 1934–35, iii., 31.

The interpretation of such a case has obvious difficulties. The association of pubertas præcox with tumours of the pineal body was emphasised by G. B. Pellizzi and v. Frankl-Hochwart and supported by the observations of other workers who have tended to regard the syndrome, when so associated, as a manifestation of hypo-pinealism. But a growing collection of cases in which the condition accompanies a hypothalamic tumour with an intact pineal gland clearly shows that the theory of hypo-pinealism is unsatisfactory. In many of the reported cases the hypothalamic tumour has been so extensive that it has not been possible to indicate a critical site for the lesion in relation to the syndrome. In 1931, however, some French observers[3] reported a case that was remarkably similar to the one described by Dr. Le Marquand. They concluded that the syndrome was referable to a functional disturbance of the ventral part of the hypothalamus and of the mammillary bodies. This view is strongly supported by the present case and appears at present to be the only tenable hypothesis.

SODIUM AND THE SUPRARENALS

THE value of common salt in what has been called "medical shock" has been known for over a century, for in 1831 W. B. O'Shaughnessy used intravenous injections of physiological saline in treating cases of cholera which was then raging in Newcastle. Since that time beneficial results have been noted in many conditions which give rise to this syndrome, but it is only recently that its value in Addison's disease has been recognised,[4] although L. Soddu[5] found that salt solution prolonged the lives of adrenalectomised animals as long ago as 1898. R. F. Loeb, D. W. Atchley, and J. Stahl[6] have recently reviewed the relationship of sodium to adrenal insufficiency. Loeb showed in 1932 that the acute crises of Addison's disease were associated with a sharp fall in the blood sodium, that such crises could be precipitated by withdrawal of salt and mitigated by its administration. Experimental studies on adrenalectomised dogs showed a rapid fall in blood sodium after removal of the second suprarenal; this was accompanied by a drop in the chloride and bicarbonate and a rise in potassium and non-protein nitrogen. The sodium deficiency was due to a greatly increased urinary excretion, but the nitrogen retention could not be accounted for by the usual hypothesis of prerenal deviation of water as the urinary volume was above normal. The mechanism of this abnormal sodium excretion was investigated; it was found not to be due to liberation of some abnormal acid requiring fixed base for its elimination, as the urinary ammonia showed no rise; nor was it due to diuresis as the amount of sodium excreted was relatively greater than the amount of water. The authors fall back on the explanation that the suprarenal cortex controls sodium metabolism as the parathyroids do calcium. A point of interest which emerges from some unpublished experiments is that the biochemical changes following salt withdrawal in adrenalectomised dogs are identical in character with, though less in degree than those following withdrawal of cortin. Loeb and his colleagues reach the following conclusions which are of considerable clinical significance: that a low blood sodium, although constant in Addison's disease, is not diagnostic of it; that the diagnostic test of salt withdrawal as suggested by Harrop and others[7] is too dangerous to be used; that any intercurrent infection in a patient with Addison's disease increases the requisite maintenance dose of salt or cortin, thus forming a parallel with diabetes and insulin and tetany and parathormone; and finally that if adrenal insufficiency in man be not relieved by salt it will not be relieved by commercial cortical extracts in ordinary doses. This latter statement should act as an incentive to the production of extracts of greater potency, for it is still true to say that though much may be done for sufferers from Addison's disease, the majority of cases eventually die of the condition.

THE FUTURE OF PHARMACY

IN his presidential address to the British Pharmaceutical Conference last week the chairman, Dr. F. W. Crossley-Holland, briefly sketched the development of the modern pharmacist. Three hundred years ago, he said, there were three classes of people concerned in the care of the sick: the physician who prescribed, the apothecary who dispensed, and the chemist or druggist who supplied the drugs. In course of time, and after a struggle whose acrimonious repercussions echo in the pages of Culpepper, the apothecaries attained the right of prescription as well as of dispensing and became the forerunners of the modern family doctor. Neither the physicians nor the transfigured apothecaries established any professional or social contact with the vendors of drugs and "the heritage of the practice of pharmacy from the practice of medicine contains the elements of a former dislike and distrust." None the less, as Sir Henry Dale pointed out in his address to the Pharmaceutical Society early this year, there was for a long time the "most simple and natural cöoperation" between the pharmacist and the medical practitioner. Developments over the last quarter of a century are tending to change this relationship, for there is a continuous shrinkage in the prescription of the old-fashioned remedies compounded by the chemist himself. Sera, vaccines, and biological substances of many sorts play an increasingly important part in medicine, and in addition many synthetic drugs are available to take the place of older remedies; in the handling of all these the pharmacist plays the part of a distributor only. Dr. Crossley-Holland warned his hearers that this process is likely to continue and looked about for means of establishing a new link between the pharmacist and the practitioner of medicine. He regarded the falling-off in the demand for "drugs and galenicals" as bearing a relationship to the present "trend of medical thought and practice," this trend apparently being a preference for specific as opposed to symptomatic treatment.

Specific treatment demands accurate diagnosis, and looking about for means of establishing a closer rapproachement with the practitioners of medicine Dr. Crossley-Holland developed the thesis that pharmacists should turn their attention to medical diagnosis. "It would," he said, "be of the greatest assistance to the doctor if he could depend upon the pharmacist to undertake the examination of body secretions and excretions, to examine pathological urine and other morbid products . . . . carry out blood counts and generally to engage in the conduct of laboratory aids to diagnosis." But whether this is work properly to be undertaken by a pharmacist, however skilled in his own profession, is open to question. As Dr. Crossley-Holland said, it requires knowledge and manipulative skill; and though the pharmacist must possess the latter his present training is not calculated to fit him to deal with diagnostic problems. In fact nothing short of a full medical training can do that.

SOCIETY OF MEDICAL OFFICERS OF HEALTH

WE have received a communication from Dr. R. Veitch Clark, president, and Mr. G. L. C. Elliston, secretary, of the Society of Medical Officers of Health, stating the policy of the Society undertaken in behalf of public health medical officers which they believe to have the approval of the public health service. The writers set out the aims of the Society, its services in behalf of the public and its members and its freedom from political bias. And they call attention to the coöperation existing between the British Medical Association and the Society, in view of the activities of a medical body, which they do not name, but which they assert is for the first time claiming to represent the interests of public health medical officers. The council of the Society, through the president and executive secretary, are therefore reaffirming their position, drawing the special attention of public health medical officers to a leading article on the subject which appeared in the *British Medical Journal* of June 1st (p. 1127). "They feel that it is of the utmost importance that both public health medical officers and local authorities should not be confused by the arbitrary action of another medical body in putting forward a new salaries scale and a new method of negotiation, the adoption of which is being urged upon medical men and local authorities on grounds not dis-associated from politics." The council believe that it is unnecessary to appeal to the loyalty of the fellows towards securing that their present objects and methods of action are adhered to. With regard to the main practical point in which the coöperation between the B.M.A and the Society of Medical Officers of Health exists, namely, that of the scale of salaries, a scheme arranging the scales was adopted in 1925, has been in existence ever since and has always been supported by THE LANCET.

SURVIVAL BY PERFUSION

HITHERTO the perfusion of isolated mammalian organs has been limited to experiments of short duration owing to the numerous conditions which militate against the indefinite maintenance of an artificial circulation. The difficulties lie not so much in the attainment of asepsis as in the gradual deterioration of the preparation from other causes; in an experiment which is only going to last for a few hours aseptic precautions are usually regarded, perhaps wrongly, as a waste of time. Either as a result of procedures to render it incoagulable, or because it is circulating in an unnatural environment, the shed blood used for the perfusion develops "toxic" properties which lead to progressive vasoconstriction and œdema in the isolated organ. For this reason lungs are usually inserted in the circuit to "detoxicate" the blood, but they also become œdematous in time; J. de B. Daly believes the toxic properties to be due to the precipitation of some solid material which is filtered out by the lungs, and has successfully replaced these by filters, but it is doubtful whether this is a complete solution of the problem. Another important factor is the intermittency of the circulation. It is well known that a mere head of pressure equal to the arterial pressure is useless for prolonged perfusion, and that a pulsatile flow must be provided. Owing to the almost inevitable inclusion of rigid glass tubes in the circuit, it is impossible to guarantee that a mechanical pump will reproduce the heart beat exactly from the point of view of the organ; moreover, although immense improvements in perfusion pumps have been made, a certain degree of trauma to the blood is inevitable, and this may have something to do with the development of its toxic properties. Therefore as we pass from the heart-lung to the pump-lung, and from this to the pump-oxygenator circuit which contains no vital tissue except the organ under investigation, the difficulties of even short perfusions increase enormously. Even when "successful" the organ is not necessarily working normally; thus the kidney secretes urine, but it is not normal urine. These are but the outstanding and well-recognised difficulties, and the claim recently reported from Dr. Alexis Carrel's laboratory in the Rockefeller Institute, New York, that organs have been kept alive under artificial conditions for as long as twenty days implies that the additional problem of elimination of metabolites has been solved and that one of the most sensational advances in the history of physiology has been made. The details of the Carrel-Lindbergh "life-chamber" will be awaited with keen interest to all those engaged in the study of normal and abnormal function.

THE Dr. Jessie Macgregor triennial prize in medical science has been awarded to Dr. Mary Broadfoot Walker, of St. Alfege's Hospital, London, for her work on physostigmine in the treatment of myasthenia gravis.

THE death is announced at Philadelphia of Prof. Thomas McCrae, physician to the Jefferson and Pennsylvania Hospitals, Philadelphia, whose collaboration with Sir William Osler in the production of the "System of Medicine" has made his name deservedly familiar to the medical world. Prof. McCrae was 65 years of age.

A DOMINION LUNCHEON.—Three medical men who have held, or are holding, high office in the Dominions—namely, Sir Stanley Argyle, late Premier of Victoria, Dr. H. A. Bruce, Lieut.-Governor of Ontario, and Mr. S. M. Huggins, Prime Minister of Southern Rhodesia—were entertained at a luncheon given at Grosvenor House, Park Lane, on June 27th, by officers of the British Medical Association. Those present included Mrs. Bruce, Lord Dawson, Sir Humphry Rolleston, Sir George and Lady Badgerow, Sir Harry Batterbee, Sir Henry and Lady Brackenbury, Sir Thomas and Lady Dunhill, Sir Thomas Stanton, Sir Holburt Waring, Dr. and Mrs. G. C. Anderson, Mr. and Mrs. Rowley Bristow, Dr. Alfred Cox, Dr. and Mrs. J. S. Fairbairn, Mr. and Mrs. L. Ferris-Scott, Mr. and Mrs. Bishop Harman, Dr. C. O. Hawthorne, Dr. and Mrs. Robert Hutchison, Dr. and Mrs. E. K. le Fleming, Dr. and Mrs. W. Paterson, Dr. S. Watson Smith, and Mr. H. S. Souttar.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LIX.—PROGNOSIS IN STREPTOCOCCAL INFECTIONS OF THE SKIN

In a consideration of eruptions caused by streptococcal infection two groups must be differentiated: (1) those due to invasion of the skin by living and actively multiplying organisms; (2) those which are cutaneous reactions to streptococcal toxin, absorbed from some focus of infection, or to the organisms themselves circulating and reaching the skin in the blood stream. The latter group I have termed streptococcides (THE LANCET, 1921, ii., 483), thus bringing them into line with the tuberculides, trichophytides, and levurides, although Sabouraud has unfortunately employed this term to indicate certain *external* streptococcal infections.

In this article the first group only will be considered. Unlike certain strains of staphylococci (*Staph. cutis communis*), streptococci are not normal habitants of the skin, although some varieties are constantly present on the mucous surfaces of the mouth, throat, and intestine (*Strep. salivarius, fæcalis, &c.*). Like the more virulent strains of staphylococci (*Staph. pyogenes aureus*), however, pathogenic streptococci (*Strep. pyogenes longus*) are frequent invaders of the skin, where they may cause lesions of various types. Certain differences between staphylococci and streptococci as regards their infection of the skin may be tabulated as follows:—

STAPHYLOCOCCI	STREPTOCOCCI
1. Some strains may be considered as natural habitants of the skin.	1. Are more likely to invade the skin either from some previous host, or from mucous membranes.
2. Tend to involve the pilo-sebaceous follicles, so that most staphylococcal eruptions are primarily follicular.	2. Have no predilection for the follicles, but tend to involve the natural folds of the skin and the muco-cutaneous junctions, and to cause fissures.
3. Do not, as a rule, cause lymphangitis or adenitis.	3. Are prone to invade the lymphatics and cause adenitis.
4. Are powerfully chemiotactic for polymorphonuclear leucocytes, thus producing "laudable pus."	4. Are less pyogenic, and tend to provoke an exudation of serum, containing only a few cells.
5. Staphylococcal lesions usually remain *pure*—i.e., do not become secondarily infected with other organisms.	5. Streptococcal lesions always become secondarily infected with staphylococci.

The following streptococcal affections of the skin will be considered: (1) impetigo contagiosa; (2) impetigo pityrodes; (3) ecthyma; (4) intertrigo; (5) fissure; (6) erysipelas (acute); and (7) recurrent streptococcal lymphangitis or relapsing erysipelas.

Many writers include the bullous impetigo of the newly born, or pemphigus neonatorum, among the cutaneous streptococcal infections, but a number of careful independent observations tend to incriminate the *Staphylococcus aureus* as the causal organism (T. H. C. Benians and B. H. Jones: THE LANCET, 1929, i., 174).

IMPETIGO CONTAGIOSA

This is caused by a superficial invasion of the skin by a *Streptococcus pyogenes longus*, the site of infection being just beneath the horny layer. In most cases the disease runs an acute and self-limiting course of some three to six weeks' duration, recovery taking place spontaneously owing to the gradual development of immunity to the infecting streptococcus. I am aware that this statement will be challenged by many, particularly by the advocates of this or that method of local treatment, but in the acute attacks to which I refer I have not discovered any topical application that will entirely prevent the appearance of new lesions. When I was in the Persian Gulf in 1916 at the hottest time of the year I had a very severe attack of impetigo, and all my therapeutic efforts were in vain, for new lesions continued to appear over a period of several weeks. Within forty-eight hours of my arrival in Bombay, however, striking improvement was manifest, and recovery was rapid. On the other hand, I believe that it is possible to abort an attack in the early stages by giving either a few intramuscular injections of Aolan, or a mixed streptococcal and staphylococcal vaccine at short intervals.

It is important to remember that impetigo contagiosa of the beard or moustache regions in men may result in a sycosis, the secondarily invading staphylococci becoming established in the hair follicles, and this risk must be combated not only by suitable local treatment, but also by measures designed to raise the patient's resistance to pyogenic infection. In certain cases recovery from an acute attack of impetigo is incomplete, a few persistent and indolent lesions remaining and being often associated with chronic streptococcal fissures in the natural folds—e.g., in the retro-auricular space, or at a muco-cutaneous junction, such as the angles of the nostrils or the labial commissures. An out-of-door holiday in a bracing climate and a generous vitamin-rich dietary will usually succeed in these cases.

IMPETIGO PITYRODES

It is to Sabouraud that we owe the recognition of this dry, attenuated form of impetigo. It is usually situated on the face, and the lesions consist of dry, furfuraceous patches of circular or irregular contour. Probably the majority of cases of the *dartre volante* or "tetter" of older authors were impetigo pityrodes. They are met with towards the end of an attack of ordinary impetigo, and one may see in the same patient all stages, from the crusted, oozing lesions, to the dry, scaly patches referred to. They are, however, also common in children suffering from chronic nasal catarrh, in whom there has been no definite attack of ordinary impetigo, and are then frequently associated with streptococcal fissures at the angles of the nostrils or mouth. Their occurrence is predisposed to by the use of strong alkaline soaps, which damage the protective horny layer, but such soaps may of themselves give rise to dry, scaly patches apart from infection. Impetigo pityrodes is contagious, and many epidemics of it have been described. It has to be differentiated from the scaly patches caused by the pityrosporon of Malassez, which are usually seen in older children and adults, and from the eczematoid form of lichen scrofulosorum (dermatitis scrofulosa).

This attenuated form of impetigo is often much more resistant to treatment than the acute variety, probably because the mildness of the infection does not stimulate the defensive reactions on the part of the host necessary to produce immunity. It is well known that spontaneous recovery usually occurs if the patient be sent to some bracing place on the east coast, and I am convinced that a diet relatively rich in carbohydrate, with an inadequate supply of protein and of vitamin-containing foods, is a predisposing factor in this condition, as it is in the chronic catarrh of the upper respiratory tract that so often accompanies it. As regards local treatment, I have found that painting the patches daily with a 1 per cent. solution of iodine in spirit, followed by the application of an ichthyol cream or paste is effective. Alkaline soaps should not be used for washing the face.

ECTHYMA

This is merely a deep form of impetigo in which destruction of the epidermis occurs and an ulcer results; consequently the lesions leave scars after healing. They occur usually on the legs, and circulatory stasis is an important contributory factor, so that they are common in persons with acro-asphyxia, and on varicose legs, where they may be the starting point of chronic varicose ulcers. During the war ecthyma was a very frequent complication of pediculosis, and the *Streptococcus fæcalis* was often the infecting organism (H. MacCormac). The lesions will usually heal under antiseptic applications—e.g., a 1 in 4000 solution of perchloride of mercury applied as compresses after removal of the crusts. In obstinate cases, where as a rule the patient is debilitated, exposure to sunlight or the ultra-violet rays is of value.

INTERTRIGO AND STREPTOCOCCAL FISSURE

With the relapsing lymphangitis to which they predispose, these are the commonest chronic conditions caused by streptococcal infection of the skin. They may, indeed, be regarded as the cutaneous manifestations of chronic streptococcal infection of epithelial structures, which is one of the most difficult of all diseases to cure. As an example, the following case, already described by me in the Guy's Hospital Reports, 1931, lxxxi., 92, may be quoted :—

> A lady, aged 28, had scarlet fever at the age of twelve, and from that time had suffered more or less continuously from so-called "eczema" of the ears. She has had five attacks of erysipelas of the face. Before her marriage there was some leucorrhœa, and, since the birth of one of her two children, there has been a thick vaginal discharge. Unless this is checked with a cotton-wool plug she develops "eczema" of her groins. She has also periodically had the "eczema" in the submammary folds. On examination she was found to have (1) typical retro-auricular intertrigo, obviously of streptococcal origin, with chronic *meatitis*; (2) at the upper angles of the nostrils were the remains of streptococcal fissures, doubtless the portals of entry of infection responsible for her attacks of recurrent erysipelas. The "eczema" of her groins and submammary regions to which she was subject were clearly also streptococcal intertrigo. The vaginal discharge was found by Mr. F. Cook to be due to a chronic cervical erosion. Prof. Eyre recovered a *Streptococcus pyogenes longus* with other organisms from the retro-auricular intertrigo and the nasal fissures.

This case illustrates very well the persistence over a period of sixteen years of a streptococcal infection of the skin dating from an attack of scarlet fever. The patient was very lucky in that her repeated attacks of erysipelas, arising from neglected nasal fissures, did not lead to permanent blockage of the lymphatics of the malar regions and eyelids. The patient's sister was also under my care for chronic retro-auricular intertrigo.

The prognosis as regards cutaneous lesions in chronic streptococcal infection is more favourable than where the mucous membranes are involved, but even so relapse is common, particularly in those who are compelled to live sedentary indoor lives. As has already been indicated, I believe that diet and environment are important factors, and I am convinced of the value of vaccine therapy, if it is employed judiciously and for a sufficient length of time. An important point is that the local treatment of intertrigo and fissure must be continued until a normal epithelium has been re-established, for otherwise relapse is certain.

ACUTE ERYSIPELAS

Severe cases of erysipelas, ending sometimes fatally, are less common than formerly, and I do not think that this is entirely due to more effective treatment. Possibly the diminution of chronic alcoholism may be partly responsible. A. Rendle Short (Index of Prognosis, 1915) states that the mortality in 875 cases at St. Bartholomew's Hospital, collected several years ago, was 3·5 per cent. In cases in which there was an accompanying cellulitis it was much higher—11 per cent. in 889 cases. W. H. Guy (Jour. Cut. Dis., 1919, xxxvii., 399), D. Symmers and K. M. Lewis (Jour. Amer. Med. Assoc., 1927, lxxxix., 880) and others have emphasised the therapeutic value of streptococcal antitoxin. H. Semon has recorded the remarkable effect of intramuscular injections of aolan in a case in which a fatal result had been anticipated, and in recent years I have employed this method of treatment in several cases of varying severity with uniformly good results. In the absence of unfavourable conditions, such as alcoholism, diabetes, chronic renal disease, long-standing malnutrition, and cachexia, the prognosis in acute erysipelas may be regarded as very favourable.

RECURRENT STREPTOCOCCAL LYMPHANGITIS (RELAPSING ERYSIPELAS)

This is one of the most important and serious complications of chronic streptococcal infection of the skin, because the repeated invasion of the lymphatics may eventually cause their blockage, giving rise to persistent elephantiasis and consequent disfigurement. The streptococcal fissure is the usual portal of entry to the lymphatics. When these occur between the toes, they are usually secondary to epidermophytosis. They may cause recurrent attacks of lymphangitis of the feet, ankles, and legs, the origin of which is often overlooked. I have recently seen two cases in which permanent blockage of the lymphatics with the production of elephantiasis had occurred from this cause, and in both the interdigital fissures and mycotic infection had been disregarded. The importance of thorough treatment of interdigital epidermophytosis is thus manifest, since it may in this way be indirectly responsible for permanent, though partial, disablement.

Recurrent lymphangitis, however, most frequently occurs on the face, giving rise all too often to persistent elephantiasis ("solid œdema" of Hutchinson). This condition has long been recognised under various terms—e.g., erysipelas perstans faciei (Kaposi), erythema perstans faciei (Kreibich), lymphangitis faciei (Mackenzie). The parts affected are usually the malar regions and the eyelids, and exposure to cold is certainly a factor predisposing to the attacks. In the great majority, if not in all cases, the portals of entry for infection of the facial lymphatics in this area are fissures at the angles of the nostrils. I am aware that cases have been recorded in which it was stated that no such fissures were apparent, but I believe that a careful examination with a strong light of the nasal vestibules at the time of the attacks will almost invariably reveal them, and, as a rule, they are seen even in the intervals. They are often associated with impetiginous anterior rhinitis, chronic nasal and nasopharyngeal catarrh, and sometimes with sinusitis. Their treatment is of paramount importance, since a repetition of the attacks of lymphangitis will in time inevitably lead to lymphatic blockage and permanent disfigurement. Less commonly, relapsing erysipelas involves the ear, neck, and side of the face, and is then due to chronic or recurrent fissures below the lobe of the ear, or in the retro-auricular space. Involvement of the lips may occur from chronic fissures at the labial commissures (*perlèche*), or in the centres of the vermilion borders.

The prognosis is in these cases good, providing that persistent blockage of the lymphatics has not already occurred. Thorough treatment of the fissures with a silver nitrate paint and a mercurial ointment or paste should be carried out until a normal epidermis has re-formed. In obstinate cases a few fractional doses of X rays are sometimes helpful. Even when blockage has not yet occurred, local treatment may well be combined with injections of an autogenous or a mixed stock streptococcal vaccine, which in my opinion give better results if made intradermally. In my experience these cases are extremely sensitive to the vaccine, and even very small doses are likely to produce a local necrosis at the site of the intradermal injections and a flare up of the lymphangitis.

When persistent lymphatic œdema is already established the prognosis is much less favourable. In some cases, however, I have had good results with intradermal injections of streptococcal vaccine, given over a long period in gradually increasing doses. In America injections of *Streptococcus erysipelatis* toxin have been favourably reported upon in these cases, and G. C. Andrews (Diseases of the Skin, Philadelphia, 1930) states that they are "a specific method for the prevention of recurrences and the reduction of persistent lymphœdema in cases of chronic recurrent erysipelas."

H. W. BARBER, M.B., F.R.C.P.,
Physician for Diseases of the Skin, Guy's Hospital.

SPECIAL ARTICLES

NATIONAL ASSOCIATION FOR THE PREVENTION OF TUBERCULOSIS

THE twenty-first annual conference of this association was held at Southport from June 27th to 29th, under the chairmanship of Sir ROBERT PHILIP, the general subject for discussion being the

Responsibility of the Nation towards the Child in Respect of Tuberculosis

Dr. G. LISSANT COX (Lancashire) said it might readily be supposed that the sub-standard child, as compared with the normal child, was more likely to be infected by, and die of, tuberculosis either as a child or later as an adult. This did not appear to be so, as a special survey made in Lancashire had shown. But since infection might lead to disease, it was of the greatest importance to safeguard the child. It was known that under certain conditions there was a very high non-pulmonary tuberculosis death-rate in young children subject to infection from mother or father. Further, in an investigation into "contacts," it had been shown that at least 15 per cent. of known cases of pulmonary tuberculosis gave rise to secondary cases, in spite of modern antituberculosis measures, the average interval between the discovery of primary and secondary cases being 3½ years. The three factors on which methods of prevention were based were isolation, immunisation, and environment. In Lancashire they had taken as their basic principle the words: find, isolate, educate, and treat the *adult positive case.* They had always concentrated on the adult positive case, believing that this safeguarded the child. Dr. Cox briefly described the various methods of isolation—the Grancher system, hospital or sanatorium isolation, or village settlements for the whole family. With regard to the provision of hospital isolation, the number of beds which should be available throughout the country was one for every death from tuberculosis. At present only a very small minority of tuberculosis workers in this country advocated inoculations for immunisation, and the speaker thought that the present state of knowledge did not warrant a large or routine use of this method of safeguarding children against infection. The principle of environment was at least as important as that of isolation. It had been shown conclusively that a higher standard of living and of housing was a direct safeguard against infection, and to this factor was largely due the great diminution which had already occurred in the incidence and mortality of tuberculosis.

Dr. M. SKOKOWSKA-RUDOLF (Warsaw) pointed out that the two peaks of tuberculosis mortality in childhood were in the first year of life (decreasing during the 3–7-year period), and in adolescence. Preventive efforts should be directed chiefly towards these two periods. Poland had adopted Calmette's system of B C G vaccination, while among other suggested provisions for the protection of tuberculous children and those in danger of infection were the following: (1) to instal for every 100,000 of the population three pairs of beds for expectant mothers (suffering from tuberculosis) and their infants, in order to allow of proper B C G vaccination and instruction of the mothers in nursing their babies; (2) to instal 12 beds for every 100,000 of the population for inoculated children; (3) to provide a minimum of 5 hospital beds for tuberculous children of pre-school age (3–7 years) for every 100,000 of the population; (4) to provide 10 sanatorium beds for every 100,000 of the population; (5) to create forest school preventoriums for children of school age, taking as standard 40 beds for every 100,000 of the population; and (6) to instal as auxiliary establishments "half sanatoria" (day and night sanatoria). These institutions were already doing good service in the big cities of Poland, children from tuberculous families spending the greater part of the day in them.

BOVINE TUBERCULOSIS

Major A. B. MATTINSON, F.R.C.V.S., spoke particularly on infection through the milk-supply. Assuming as approximately accurate the statements that any cow giving tuberculous milk to-day would be dead within a year, that any cow affected with tuberculosis to-day would be dead in five years, and that almost every cow which would be giving milk in 1940 was either unborn or was at present free from tuberculosis, certain lines of progress were indicated, including an overhaul or at least a tightening up of the various Acts and Orders. Major Mattinson outlined many ways in which the incidence of clinical bovine tuberculosis might be brought under control, urging adequate veterinary supervision of dairy herds with the object of reducing clinical—and not merely mammary—tuberculosis at its earliest manifestation.

Dr. NATHAN RAW (London) said that while no animal could be given an immunity to a lethal dose of virulent bacilli, it could be given an immunity sufficient to resist a mild form of infection, which was the usual method by which the animal was attacked. The immunisation of calves was simple, the method Dr. Raw adopted being the injection of

GENERAL CONSIDERATIONS

In 11 of the 22 cases of gold purpura a previous course of aurotherapy had been given, and this is suggestive of sensitisation. The small precipitating dose in our case of gold purpura is in favour of this view, and it is clear that the initial doses of a repetition course should be given with caution.

Probably there is some idiosyncrasy or abnormal sensitivity to these drugs. Simple toxicity of the compounds is ruled out, for some patients will tolerate nearly a full course, whilst others will tolerate one course and evince symptoms early in a second. French authorities lay great stress on family and clinical histories showing evidence of idiosyncrasy or allergy and advise against giving these drugs where there is a history of—e.g., asthma or urticaria. There was no history of any of these abnormalities in either of the cases recorded here.

Purpura in tuberculous patients treated with gold has been attributed to tuberculous bacillæmia, but Weil [1] could find no report of bacilli having been cultured from the blood investigated from this point of view. It has also been suggested that the gold may liberate tuberculous toxins, but there is no evidence that the drug acts in this way.[5]

The way in which the hæmorrhagic state is produced remains doubtful. Apparently it is not due to the anticoagulative properties that these compounds have on blood in vitro; for in the pamphlet enclosed in the sulfarsenol carton, under the heading "blood transfusion," it is recommended that 0·06 g. of sulfarsenol should be added to each 100 c.cm. of whole blood, so as to dispense with sodium citrate and give the patient the advantage of a dose of arsenic. I am unable to find a record of purpura caused in this way. Gold compounds have the same property, for Tzanck [6] says that 0·1 g. of allochrysine will prevent coagulation in 100 g. of blood in vitro; but Weil,[1] using a rabbit, found that only Solganol A. was the only one which diminished coagulation in vivo.

Sex-incidence is about equal: of 19 cases of arsenobenzol purpura 9 were in women,[4] and of 22 cases of gold purpura 14 were in women. Age, again, seems to have no influence, for two patients were over seventy and another was eighteen; nor has the general condition of the patient, for purpura has developed in patients treated for a small lesion of lupus, whose general condition was good.[8]

Various prodromal symptoms may occur—e.g., general malaise, nausea, headache, diarrhœa, and itching. Of the 22 cases of gold purpura 12 had prodromal symptoms, of which itching was the commonest. The interval between the last injection and the appearance of purpura varies, but the onset is sudden. In the second case, recorded above, it was only four hours. In Case 1 it was forty-eight hours. There have been one or two cases in which the purpuric or the agranulocytic syndrome has arisen up to five months after the last injection of gold [9 10]; and although this may be accidental it has happened often enough to suggest that the sequel was due to the drug. In both the cases reported here the oral and nasal hæmorrhages were so severe that blood from this source obscured any intestinal hæmorrhage.

In neither case was there any hepatic enlargement or jaundice; both complained of the extreme weakness usually associated with the agranulocytic syndrome. Neither showed eosinophilia. Lacapère [11] says that an eosinophilia of more than 6 per cent. before or during treatment should indicate caution in the the use of gold, while Houghton [12] found an eosinophilia of over 20 per cent. in every case developing a gold rash. In 10 cases of gold purpura in which a blood count was recorded, the eosinophilia was not high, and in only 2 cases[7 13] was it over 4 per cent.—i.e., 6 per cent. and 13·5 per cent. Recently Loewy[14] has published 4 cases of purpura hæmorrhagica following the use of Sedormid; the eosinophils were 27·8 per cent. and 9·4 per cent. in the 2 cases where a blood count was recorded.

Eosinophilia does not seem to be a conspicuous feature of arsenobenzol purpura and none of Bamforth and Elkington's 4 cases showed it.

PROGNOSIS

There were 10 deaths among the 19 patients with arsenobenzol purpura[4] and 10 among the 22 with gold purpura; so far the prognosis in the two types is much the same. In both the cases I report there was complete recovery, although the history and general condition was similar to that of many fatal cases. The red cells are always reduced in number, it may be below 2,000,000, and the hæmoglobin percentage is not always correspondingly low in the early stages. The extreme anæmia is not entirely due to loss of blood, though some patients, especially women, lose large quantities. Actual red cell destruction, as well as aplasia, probably takes place, and consequently the presence of polychromasia, reticulated red cells, nucleated red cells—all of which indicate bone-marrow activity—are good prognostic signs. Platelets are always reduced in number and may be absent, but our cases show that this does not influence the prognosis. Both our patients showed a leucocytosis and the ratio of granular to non-granular cells was always high. Leucopenia, as evidence of aplasia of the bone-marrow, carries a grave prognosis, the gravity rising with the proportions of non-granular to granular cells. This, with the degree of leucopenia, is the most important factor in estimating the outcome of a given case, although death may occur from cerebral hæmorrhage.

PROPHYLAXIS

The only efficient safeguard is systematic platelet counts, but the tourniquet test applied at each visit has been found useful (Hinault and Braillon [7]).

TREATMENT

Treatment should be started forthwith. Although no fresh spots appear and the hæmorrhage is lessening, procrastination is dangerous, for there may be a sudden severe exacerbation progressing to collapse and death. Blood transfusion is the most satisfactory method of arresting the hæmorrhage, and a large transfusion of 500–600 c.cm. seems to be better than repeated small transfusions. Before transfusion in our cases, we tried, without apparent effect, various remedies such as serum and liver. On the other hand in Lavastine and Reyt's case [15] the hæmorrhage stopped after a blood transfusion, but the patient's general condition failed to improve until she was given liver. All other accessory treatment had proved futile.

In view of the possibility of gastric hæmorrhage the diet should be soft, easily digestable, and supplemented by minced liver, liver extracts, and fluids containing at least four ounces of glucose daily. The liver—especially as we do not know its exact part in blood formation—should be protected, if possible, and it is therefore well to give 40 or 50 c.cm. of 25 per cent. glucose with the blood transfusion. Frequent injections should be avoided; they may lead to further hæmorrhage at the site of puncture. If there is evidence of agranulocytosis it is worth while giving sodium nucleinate or pentose nucleotide.[16] In Coste and Cahen's[12] agranulocytic case sodium nucleinate 0·5 c.cm. every other day produced a rapid response with ultimate recovery.

SUMMARY

Two cases of hæmorrhagic thrombocytopenic purpura are reported, the causative agents being gold and arsenical compounds. Other recorded cases are reviewed, but no definite reason for this complication is found, though an idiosyncrasy or abnormal sensitivity of the patient is the probable cause. The eosinophilic response present in other complications of gold therapy is less obvious in the purpuric cases; in only 2 recorded cases was it above 4 per cent. No effective prophylactic measures are known, but a history of allergic or other abnormal responses should engender caution. Blood transfusion is the most effective means of treatment; liver extracts may be given to aid blood regeneration. The white cell count is the most reliable guide to prognosis.

My thanks are due to Dr. J. Burnford and Dr. F. G. Chandler for permission to publish the two cases, and to the laboratory staff of the West London Hospital and the Victoria Park Hospital for their help.

BIOLOGICAL ACTIVITY OF DERIVATIVES OF THE MALE HORMONE ANDROSTERONE

BY R. K. CALLOW, D.Phil.

AND

R. DEANESLY, D.Sc.

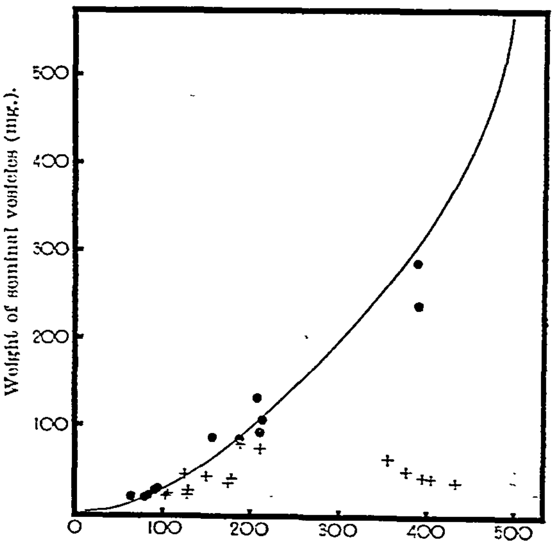
(From the National Institute for Medical Research, London, N.W.)

IT has already been shown[1] that solutions of the crystalline male hormone androsterone injected into rats will maintain normal prostate and seminal vesicles after adult castration and will produce growth of the rudimentary glands in animals castrated before puberty. Androsterone, therefore, in sufficient doses will replace the secretion of the testis, but for two reasons it was concluded that this substance is not the actual testis hormone:—

(1) It is less effective in producing growth of the seminal vesicles than of the prostate. This was seen most clearly after 28 days' injection, when the prostate was large whereas the seminal vesicles had only grown slightly (see Table and Figure).

(2) A given number of capon units of androsterone were much less active on the accessory glands of castrated rats than the same number of capon units of a particular urine concentrate.

In view of these facts it seemed desirable to test two derivatives of androsterone which by analogy with the œstrus-producing hormone might be expected to be more effective on rats: (*a*) the reduction product of androsterone, the so-called dihydroandrosterone,[2 3 4] preferably called andradiol, and (*b*) the benzoate of androsterone.



The curve shows the relation between prostate size and seminal vesicle size in normal rats. The points show the relations between these glands in pre-puberally castrated rats receiving the largest doses of androsterone (+) and andradiol (●) used in this work.

Andradiol is reported[2 3 4] to be about three times as active on the capon comb as androsterone. In agreement with this, a test in this laboratory gave a unit of 33 gamma for andradiol as compared with 100 gamma for androsterone. The Table shows the results of four experiments carried out on pre-puberally castrated rats with andradiol, and also those of five similar experiments with androsterone and one with androsterone benzoate. All details of technique are given in the previous paper.[1] It is clear from these experiments that andradiol, unlike androsterone in the dosage used, produces normal growth of the accessory glands of the pre-puberally castrated rat; the seminal vesicles grow pari passu with the prostate, and there is a normal relation between the size of the two glands (see Figure).

Table showing Average Weights after Fixation of Prostate and Seminal Vesicles in Control and Injected Rats Castrated before Puberty

No. of rats.	Daily dose mg.	Days in-jected.	Total capon units.	Average weight (mg.) of—	
				Prostate.	Seminal vesicles.
16	Controls.	—	—	16	4
6	0·6 androsterone in oil.	10	60	64	14
5	1·0 ,, ,,	10	100	112	32
5	2·0 ,, ,,	10	200	129	26
5	2·0 androsterone in alcohol.	10	200	170	56
5	1·0 androsterone in oil.	28	280	394	46
5	0·25 andradiol in oil.	10	75	63	22
5	0·5 ,, ,,	10	150	82	22
5	1·0 ,, ,,	10	300	199	101
2	1·0 ,, ,,	20	600	389	253
5	0·5 androsterone benzoate in oil.	10	—	17	5

In this respect, therefore, andradiol appears to resemble the testis hormone; but nevertheless it must be placed in the same category as androsterone owing to its low activity per capon unit on rats compared with that of the urine concentrate "Enarmon." Actually it would appear from the Table that andradiol is less active per capon unit on the rat prostate than androsterone, though rather more active per milligramme of the pure substance. On the seminal vesicles, however, after the initial lag in their growth has been passed, andradiol is much more active both per capon unit and per milligramme than androsterone, though still not as active as the urine preparation.

It follows that the high activity of "Enarmon," or of testis extracts, is not due to the presence of andradiol. This agrees with the report by the Amsterdam workers[5] of the isolation from testis of a substance, of as yet uninvestigated constitution, which is ten times as active as androsterone in capons, and which, when combined with a tissue extract, *is said to be very active on rats.*

Androsterone beznoate.—In the first test, carried out on a group of 5 capons, it was found that 272 gamma of androsterone benzoate (equivalent to 200 gamma of androsterone) given daily for five days produced negligible growth of the comb one day after the last injection. In a further test, carried out on a single capon 1·36 mg. daily (equivalent to 1 mg. of androsterone) for five days produced 5 mm. increase in length and height one day after the last injection—i.e., an effect similar to that produced by 100 gamma of androsterone. Comb growth was continued however for some time after the end of injection. The rat test on the benzoate gave completely negative results (see Table).

The increased activity of œstrone benzoate is probably due to its hydrolysis by the organism at an optimal rate. The inactivity of androsterone benzoate would indicate, however, that it is hydrolysed very slowly. Such a difference between the rates of hydrolysis of œstrone and androsterone benzoates may be correlated with the fact that the former is the ester of a phenol, whilst the latter is the ester of an alicyclic secondary alcohol. Further work is to be carried out on this subject. Analogous differences in rates of enzymic hydrolysis of phosphoric esters are known.[6]

We are much indebted to Prof. Ruzicka and to Messrs. Ciba for the supply of andradiol.

CLINICAL AND LABORATORY NOTES

A METHOD OF BLEEDING TRANSFUSION DONORS

By H. L. Marriott, M.D., M.R.C.P. Lond.

RESIDENT MEDICAL OFFICER, MIDDLESEX HOSPITAL, LONDON; ASSISTANT PHYSICIAN, MILLER GENERAL HOSPITAL, GREENWICH; AND

A. Kekwick, M.B. Camb.

CASUALTY MEDICAL OFFICER, MIDDLESEX HOSPITAL

Anyone with much experience in bleeding transfusion donors knows that it is sometimes hard to obtain several hundred cubic centimetres of blood. The method about to be described has been the standard one at the Middlesex Hospital for a year, and has rendered blood collection much easier. We have particularly found it of service in connexion with our method of continuous drip transfusion described in The Lancet of April 27th.

Difficulty in obtaining blood by needle methods arises, as a rule, either from failure to insert or maintain the needle in the lumen of the vein, or from formation of a clot within the needle. Given a sharp needle, reasonable veins, and average skill on the part of the operator, the trouble is usually from clotting in the needle. The flow begins briskly, but soon diminishes and finally stops. Our method aims at removing this difficulty by accelerating the flow of blood so that it has no time to clot. The acceleration is secured by aspirating the blood by a *strong* pump.

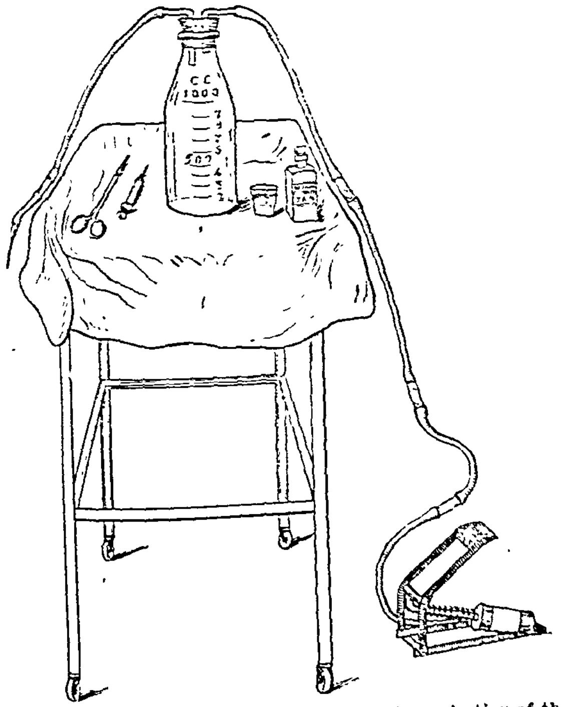
Aspiration is not a new principle, but the pumps employed have generally been weak, such as rubber bulbs of the Higginson pattern or Potain-type pumps. We employ a Dunlop "Junior" motor-car tyre foot-pump (price 18*s.* 6*d.*) with its valve reversed so that it sucks instead of blows. This pump easily provides a negative pressure of 12 inches of mercury. It has also the advantage of being foot-operated. The difference in the rate of flow made by strong suction has to be seen to be believed. It is usual to complete the collection of 500 or 600 c.cm. of blood within five minutes; a flow of less than 50 c.cm. per minute indicates that the needle is not truly in the vein. If the needle is properly inserted, the strong stream does not falter, and there is a temptation to remove too much blood because of the ease of the method.

The safe limit for blood removal by any method is *50 c.cm. per stone, or 8 c.cm. per kg. of body-weight* for healthy donors. In our experience of hundreds of cases rapid removal causes considerably fewer reactions than slow, because, provided the above limit is observed, any reaction that occurs in withdrawing blood is psychological and not due to blood loss. The psychological factor is proportional to the time taken. It is increased by prolonged manipulation, suggesting to the donor that the operator is in difficulties. Many experienced donors have commented favourably on the method from their point of view. The limit of 50 c.cm. per stone has a fair *margin of safety, but it should* be exceeded only in rare instances when the need for blood is very great and the donor is a relative of the patient. Never should it be exceeded when using the public-spirited, voluntary donors of the British Red Cross Society's transfusion service.

The simple apparatus used is shown in the illustraton.

The blood is collected in an ordinary quart milk bottle which has the advantages, as compared with special flasks, of being cheaper, stronger, and more easily replaced. The bottle is graduated in c.cm. for a few pence. The bung is of rubber. We use a Keynes's needle. All the rubber tubing is pressure tubing, for thin-walled tubing collapses under suction. The tubing between the bottle and the pump includes three sterile cotton-wool filters whose function is to prevent infection of the blood by the slight blow-back which occurs at the beginning of each stroke of the pump.

The donor should lie recumbent with one pillow. The operator, before scrubbing up, applies a sphygmomanometer cuff to the donor's arm, and blows it up to 70 mm. Hg. He also swabs the elbow flexure with spirit, and connects up the tubing to the pump, taking care to touch only the pump end of it. After he has scrubbed up, he dons a sterile gown and sterile gloves and isolates the area of the vein with sterile towels.



The apparatus used. The relative differences in projection of the glass tubes through the bung into the bottle are important and must be as shown.

The Keynes's needle is inserted into sterile 3·8 per cent. sodium citrate solution, two or three pumps given, and 100 c.cm. sucked into the bottle. A Spencer Wells forceps is then clipped on the tubing between the bottle and the glass connexion, and a good partial vacuum developed in the bottle by half a minute of vigorous pumping. Next, a wheal is raised over the vein by intradermal injection of a few drops of 1 per cent. novocain. The Keynes's needle is thrust through the wheal into the vein, and the Spencer Wells removed. Blood shoots through the glass connexion, and a moment later enters the bottle. If this does not happen, the vein has been missed or over-penetrated, and the needle must be manipulated, without withdrawal, till blood is seen in the glass connexion. Once the needle is in the vein, it is advisable gently to push it up the vein to its hilt so that a slight subsequent movement of the operator's hand may not cause the mishap of the needle slipping out of the vein.

The blood flows in a steady stream, and it is only necessary to give an occasional few pumps as collection proceeds. The donor should strongly clench and unclench his fist upon a roll of bandage about a dozen times a minute throughout the removal of the blood. If the flow stops for a moment, the needle should be given a slight twist to release the vein wall which has become sucked against the hole in the needle. The operator should control the needle with one hand, and hold the bottle with the other, so that it is below the level of the couch and out of sight of the donor. He should keep shaking the bottle to mix the blood and citrate solution.

When sufficient blood has been removed, the sphygmomanometer cuff is deflated, and the needle withdrawn. A swab is applied to the puncture, and the donor instructed to flex fully his elbow. The tubing on either side of the bung is disconnected. The top of the bottle is tied up in a sterile towel if the blood is not immediately wanted.

The closed nature of the method makes it more aseptic than the common practice of catching blood in an open jug; it also eliminates mess. The needle and tubing should be washed at once before clot forms. The donor should remain lying down for half an hour by the clock, and should drink two large cups of tea to replace the fluid lost.

GOLD SALTS IN THE TREATMENT OF ASTHMA

BY L. BANSZKY, M.D. Berlin, L.M.S.S.A. Lond.
LATE ASSISTANT TO THE CLINIC FOR ALLERGIC DISEASES, LEIDEN, HOLLAND

THE use of gold preparations for asthma was first suggested in 1930 by Dudan,[1] who found that cases of asthma with radiological evidence of previous tuberculous lesions in the lungs were greatly benefited by intravenous injections of Sanocrysin. He reported disappearance of all symptoms and return to normal in some 70 per cent. of the patients treated in this way.

The beneficial effects of the remedy can be explained on grounds other than Dudan's theory that the asthma was due to a non-active form of tuberculosis. In all diseases successfully treated with gold salts (whether tuberculosis, arthritis, actinomycosis, or asthma), the first response is an increase of body-weight, with a very definite feeling of well-being, and improved sleep and appetite. This general tonic effect would partly be sufficient to account for the improvement in cases of asthma, but there are certain facts pointing to a specific tonic effect on the vegetative nervous system. This effect I am at present investigating, but the object of the present note is simply to record the results obtained in the treatment of 20 cases.

Preparations used.—The gold preparation used was Crisalbine, which was given intravenously at weekly intervals. Reactions were prevented by increasing the dose only when the previous strength had been well tolerated by the patient. The first was 5 mg. (0·005 g.) and the highest usually 0·05 g. (in two cases 0·09 g.). Altogether approximately 0·5–0·6 g. of gold was given, distributed over 20–25 injections.

Complications.—According to Anson[2] doses up to 0·1 g. hardly ever prove poisonous, and in nearly 80 per cent. of the cases treated by him all toxic phenomena occurred with doses above 0·45 g. This agrees with my own experience that the toxic effects of gold salts in this strength are negligible. Anson's figures apply to sanocrysin used in tuberculosis, but the advantage of small doses of gold applies even more to asthmatics, who are usually much less tolerant of intravenous injections than other patients. The urine was examined before each injection and I was never able to find any albumin in it. Slight dermatitis developed in 3 cases, but it disappeared within four weeks of discontinuation of the treatment, without administration of any of the drugs usually given, and the treatment could be continued.

Results.—Of the 20 cases treated with crisalbine 10 became wholly free from asthma, with return to normal condition, and remained free from symptoms more than a year after completion of treatment.

---

[1] Dudan, A.: Schweiz. med. Woch., 1932, lxii., 96.
[2] Anson, C. E. H.: Tubercle, June, 1931, p. 385.

Of the other 10, 5 became free from asthma after the first course, but had a relapse after five or six months; 3 of them got well after a second course, though it is too soon to say whether the improvement has been permanent, but 2 did not respond to the second course. Out of the remaining 5 patients, 1 who had very severe asthma showed only partial improvement, 1 did not respond at all, and 3 had attacks of asthma as a result of each injection, so that the treatment had to be discontinued. In 8 cases out of the 20 great improvement was observed after the first injection (0·005 g. crisalbine); in other cases the improvement did not set in until after the third, sixth, or tenth injections. One patient developed asthma after 0·04 g. of crisalbine, another after 0·06 g., and another after 0·07 g. In these cases the attacks were only slight and subsided after a day or two.

My experience suggests that minute doses of gold salts are a harmless and valuable addition to the group of non-specific drugs (sulphur, iodine, tuberculin, &c.) in the treatment of asthma and deserve to rank first among such remedies.

London.

MEDICAL SOCIETIES

SOCIETY OF MEDICAL OFFICERS OF HEALTH

FEVER HOSPITAL MEDICAL SERVICES GROUP

A MEETING of this group was held on June 28th, Dr. H. S. BANKS, the president, being in the chair.

Dr. G. RONALDSON communicated observations on

The Pathogenesis of Diphtherial Paralysis

He said that the pathogenesis of diphtherial paralysis was a subject on which there was no consensus of opinion. Exponents of a central conception maintained that many points in the symptomatology admitted of no other explanation than an affection of the central nervous system, while supporters of the peripheral hypothesis were equally convinced that the paretic manifestations were the result of toxic action on the peripheral nerves. There were variants of both theories, but whether a central or peripheral view was favoured, the fact that analogous features existed between diphtheria and tetanus would be generally admitted. A brief reference to the pathology of tetanus was helpful in comprehending a view held by many leading French clinicians, viz., that diphtherial paralysis was of the nature of an ascending neuritis. In the ascending form of tetanus, the toxin was supposed to travel along the nerves from the infective focus to the central nervous system, and the first manifestations appeared in the immediate neighbourhood of the wound. The French theory of the pathogeny of diphtherial paralysis was essentially similar; it was initially an ascending nerve transport process with local symptoms of central origin. A theory which was more familiar to English readers was that of F. M. R. Walshe, who sought to adapt the Meyer and Ransom tetanus classification (local, specific, and general) to the nervous phenomena of diphtheria. The local form was exemplified by paresis of the palate in faucial cases, and this was alleged to be the result of toxin ascending from the fauces to the central nervous system by the perineural lymphatics. The specific form (oculomotor palsy) was central in origin and the generalised (polyneuritis) "sometimes central and sometimes peripheral," but the toxin in these latter types was said to be carried by the blood. Dr. Ronaldson then summarised the chief arguments in favour of nerve transport hypotheses in general. Certain recorded instances of accidental injection of diphtheria toxin had thrown some light on these questions and a number of these happenings were referred to as series A, series B, series C, and series D, which had occurred in certain foreign countries. The paretic sequelæ were almost identical with those of natural diphtheria—e.g., in series A, paresis of accommodation 3rd week; palatal paresis 3rd–4th week; peripheral neuritis 6th–9th week. As these were virtually examples of artificially produced paresis in the human subject and there could be no question of a coexisting faucial lesion, the occurrence of palatal paresis definitely refuted the argument previously mentioned. In the words of the observer of the series C cases, "extensive observations on several hundreds of cases have revealed to us paralysis of the palate and pharynx with the same frequency following injection into a point however far from the pharynx." In some cases an injection in the gluteal region had occasioned an acute neuritis with positive Lasègue's sign and paresis of the muscles supplied by the peroneal branch of the sciatic. This "local" condition was quite different from the paresis of natural diphtheria and its counterpart must be sought in the results of animal experiment where injections into the sciatic nerve had produced a comparable lesion. Dr. Ronaldson then described with comments the diphtheria toxin experiments of H. Meyer, Babboneix, and others. His conclusion was that the results of such experiments could not be dissociated from an inflammatory element which was absent in the naturally occurring disease, and the ascending process which was often referred to as characteristic had not been satisfactorily demonstrated. The work of Defrise, Jossifow, and other anatomists had disposed of the contention that the perineural lymphatics acted as pathways for toxin carriage; they had traced these lymphatics to the neighbouring lymph glands. The important tetanus researches of Abel and his associates had told us that when properly graded doses were employed, the length of the latent period was the same in large or small animals. The local sensory loss which was an occasional sequel of the Schick test had demonstrated the possibility of local action with a "time lost" factor entirely independent of any nerve travel. The nerve transport theory remained unproved and the arguments adduced in its support had no validity. The speaker then gave his reasons for asserting that a purely peripheral conception was not altogether in accordance with the known facts, though he contrasted the very constant evidence of peripheral nerve changes with the meagre and inconstant findings in the central nervous system. Extended histopathological investigations of the central nervous system in diphtheria should be carried out with the employment of modern technique; negative findings in a small series of cases did not prove the correctness of any conception. Such unusual symptoms as trismus, athetosis, convulsions, and transient hemiplegia were seen in the series B cases, and Dr. Ronaldson had published similar examples in cases of natural diphtheria. These rare phenomena were of no great clinical significance, but they showed the possibility of hæmatogenous involvement of the central nervous system, and their occurrence proved that the "blood-brain-barrier" was not absolutely impermeable to diphtheria toxin. The case for hæmatogenous central involvement was really dependent on clinical inferences and a number of suggestive clinical observations were mentioned. Various types of impairment of the palate were described. The only truly local form of diphtheritic paralysis was the precocious variety, and its pathological basis was probably a myositis which was the result of toxic saturation. What had been called the local sign or factor was quite different and the simple and most satisfactory explanation was a process of toxic diffusion. All confusion would be obviated if this type were referred to as "regional."

Dr. F. M. R. **Walshe** confined his remarks to his own clinical observations. During the war chance had given him the opportunity of seeing some 100 cases of diphtheritic paralysis following faucial diphtheria, and some 60 cases following extrafaucial diphtheria (cutaneous and wound infections.)

Of the faucial cases over 90 per cent. of those showing nervous manifestations had palatal paralysis as an early sign. Of the extrafaucial cases, none showed palatal palsy, but a third had an early palsy related anatomically to the seat of the infective focus. In addition to these there were two cases with infected cutaneous lesions in whom there had been palatal palsy in the absence of any history of sore-throat. But both of these had come under observation several weeks after the onset of their symptoms, and the absence of positive throat findings at this juncture did not exclude its probable early presence. Similarly, the absence of a history of sore-throat was not conclusive, because all were familiar with typical cases of post-diphtheritic paralysis in patients who gave no history of sore-throat. He had seen such cases himself. Therefore, it appeared to him that the only reasonable interpretation of these 160 observations was that the initial palsy in diphtheritic paralysis was of the nature of an ascending neural intoxication from the site of the infective focus. It was impossible to disregard the mass of evidence in favour of this view. The later developing multiple neuritis was probably a blood-borne intoxication and was manifestly the result of a peripheral lesion, whereas the initial local palsy was almost certainly central in origin. A study of the literature of extrafaucial diphtheria from the point of view of its nervous complications was disappointing, because the clinical descriptions were usually grossly inadequate, but even so the literature contained numerous case records which supported the view he had put forward, and—as far as natural diphtheria was concerned—no cogent evidence against it. In any case, any assessment of the nature of diphtheritic paralysis required as a background a working knowledge of other intoxications and diseases of the nervous system, and this was rarely forthcoming from those who wrote upon the subject.

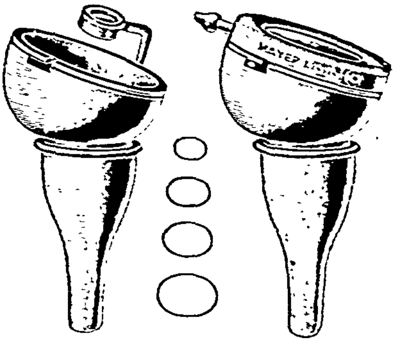
Dr. M. **Mitman** maintained that diphtheritic paralyses depended upon lesions of the central nervous system. He believed that the rapidity of onset and the extent of paralyses vary with the extent of the oropharyngeal membrane. The fixation of toxin to nervous tissue occurred early in the disease, and once fixed, antitoxin was incapable of affecting it. The latent period before the onset of paralyses was occupied by the time taken for transportation along nerves and affection of cranial nuclei. Those nuclei nearest the site of entry of toxin into the central nervous system were the earliest and most frequently and severely affected. The common sequence of paralyses—what he called "the march of paralyses"—depended upon the time taken for toxin to travel inside the central nervous system from one nucleus to another. Once the toxin was disseminated any nuclei might be affected, although the toxin appeared to exert some selective affinity. All the paralyses could be explained on this hypothesis. The so-called late cardiac failure he also attributed to a central (bulbar) involvement. In support of this view he drew analogies with other diseases of the central nervous system: tetanus, acute poliomyelitis, and lead palsy, and brought forward several clinical, pathological, and experimental arguments in its favour. He mentioned a case of severe diphtheria in which diaphragmatic paralysis was followed by paralysis of the upper intercostals and then of the lower. This suggested to him a progression of the process downwards in the cervical cord. He had seen unilateral paralysis of the palate, eye, or other structures appearing on the side of the original faucial membrane. He held that this was the rule and depended upon a nerve transportation of toxin to one side of the central nervous system. If the faucial affection was bilateral, the unilateral paralysis would appear on the side which had had the more extensive membrane. Sometimes paralysis occurred on one side before the similar structure on the other side was affected. The side of the earlier paralysis was the side of the more extensive membrane. If these findings were accurate they could only be explained by a central nervous lesion.

NEW INVENTIONS

A MODIFIED SIEGEL'S SPECULUM

The features of the speculum shown in the accompanying figure are:—

1. *An opening in the upper part to facilitate rarefaction of air inside the ear.*—The procedure is as follows. The speculum having been placed in the ear, the rubber bulb attached to the speculum is pressed with the right hand and completely emptied of air, the latter escaping through the opening. The opening is next closed with the index-finger of the left hand, the bulb is released and the air thus drawn from the ear into the bulb; during this process discharge is coaxed from the middle ear into the meatus. A very powerful suction is obtained in this way: "sticky discharge" of Eustachian or attic origin is easily drawn into the meatus. I found this speculum particularly useful when preparing the ear for ionisation. With Siegel's speculum I only succeeded in moving the discharge to and fro without being able to detach it from the compartments of the middle ear.



2. *A magnifying lens.*—A revolving magnifying lens is incorporated in this speculum. To bring it into action the top part is removed and the lens revolved into the line of vision: the lens enables the surgeon to remove impacted wax or polypi, or to cauterise granulations with great facility.

The speculum was made for me by Messrs. Mayer and Phelps, of New Cavendish-street, W.1.

London, W.　　**Arthur Miller**, F.R.C.S.

REVIEWS AND NOTICES OF BOOKS

Entstehung und Funktion von Gefässsystem und Blut auf Cellular-Physiologischer Grundlage

By Dr. Med. MAX HAUSMANN, St. Gallen. Basel: Benno Schwabe and Co. 1934. Pp. 704. Rm. 44.80.

THE genesis of the circulatory system and of the blood is here traced back to rudimentary beginnings in invertebrate forms. The problems involved are discussed at length from both morphological and physiological aspects. The work is divided into three main parts: in the first the author examines the morphology and histology of the cœlomic system in all the principal invertebrate types; in the second the development of the vascular system in primitive vertebrates is described, while the third gives a remarkably complete account of the physiological aspects of the circulatory system in the higher vertebrates.

It is difficult to give an adequate impression of so comprehensive a work: the canvas is vast and full of detail. Dr. Hausmann takes the view that the vascular endothelium of the vertebrates is derived phylogenetically from the cœlomic elements of more primitive forms. Following Lang's trophocœle theory he finds that the cœlom is productive of endotropic and exotropic formations. The latter leads to the appearance in the animal kingdom of the so-called hæmocœle and hæmocytes which evolve later into the vascular system and its various components. The blood-cells spring in part from the primitive mesenchymal cells and in part from the vessel wall itself by proliferation. It is interesting to find that the author regards the reticulo-endothelial system as essentially primitive. According to him the phagocytosis and storage of dyes is a feature of primitive cell forms, and is seen in the relatively undifferentiated mesenchyme of the humbler invertebrates. In higher forms the elaboration of different types of connective tissue has tended to suggest falsely that the reticulo-endothelial system is a specialised product. Numerous other sidelights are thrown upon current medical teaching: an instance may be given in the interesting analogy traced between the land vertebrate's hypophysis and the sub-neural gland of fishes. The latter is directly exposed to currents of sea water and acts as a sort of sense organ, regulating the animal's water metabolism. It may be more than a coincidence that the hypophysis of higher forms, and related structures in the floor of the third ventricle play an important part in the control of the water balance of the body.

The book will principally appeal to the zoologists and biologists as a noteworthy study in comparative morphology and physiology. But it will also attract those whose chief interests are elsewhere but who maintain a philosophical interest in the animal kingdom. The book is well produced and lavishly illustrated; it deserves a better binding.

Traité de gastroscopie

et de Pathologie Endoscopique de l'Estomac. By FRANÇOIS MOUTIER, Chef de Laboratoire de la Faculté de Médecine. Paris: Masson et Cie. 1935. Pp. 347. Fr. 120.

THE subject of gastroscopy was brought prominently to the notice of many members of our profession during the discussion at the Royal Society of Medicine this winter, when Prof. Arafa, of Egypt, gave a demonstration and lauded the value of this method. Those requiring complete technical details concerning the use of the gastroscope will therefore welcome this book by Dr. Moutier.

In his introduction to the work Prof. P. Duval writes: "Gastroscopy should now be one of the ordinary clinical methods of examining the stomach. It occupies a similar place to radiology; it is neither superior nor inferior in value to this, it is the indispensable complement." It is essentially in helping us to determine the presence of gastritis and to estimate its real importance that gastroscopy promises to be of value; this volume, which is abundantly illustrated with coloured plates, should prove extremely useful to those wishing to pay closer attention to the lining of the stomach. Whether the enthusiasm for gastroscopy of its author and of his medical and surgical colleagues at the Vaugirard Hospital in Paris is fully justified time alone will show. For the moment it suffices to say that this treatise is the most up-to-date work available on this subject.

A Brief Outline of Modern Treatment of Fractures

By H. WALDO SPIERS, A.B., M.D., Professor of Orthopædic and Fracture Surgery, College of Medical Evangelists, Los Angeles, California. London: Baillière, Tindall and Cox. 1935. Pp. 129. 9*s*.

THE aim of this small text-book is to subtract from the rather confusing welter of methods and apparatus described by various surgeons those that are of proven value; to introduce these to the student in a clear and simple manner, so as to avoid burdening his mind with unnecessary detail; and to leave in his mind a knowledge of the fundamental principles involved in treating fractures. To a large extent these aims have been realised; but the result has not been to produce a particularly elegant or pleasing text-book. Too much can be sacrificed to brevity, and it is doubtful whether the descriptions of treatment are sufficiently detailed to be of much value to the casualty officer or to the young practitioner in his first attempts at fracture treatment. As a text-book for the examinee who requires a rapid general survey of the subject, the book has more to recommend it. The outline drawings are definite and clear, but they are, on the whole, poorly drawn; moreover the style of presentation, notably the construction of paragraphs in a series of choppy sentences, calls for improvement. Little fault will be found with the particular methods recommended in individual fractures; those chosen are, on the whole, the most generally popular. The explanation, if such it can be termed, of the occurrence of "neurotic spine" is curious. It is said that it "probably goes back to the subconscious fear which in tribal days the individual had, due to the severe penalty which usually accompanied a disabling injury of the back. A member of the tribe whose back was disabled was known to be an economic liability in those days and in all probability his life was routinely sacrificed." An ingenious suggestion but hardly convincing.

THE LANCET

LONDON: SATURDAY, JULY 13, 1935

THE ADVERTISEMENT OF SECRET REMEDIES

THE exploitation of sick persons by preying upon their ignorance, their credulity, and their morbid hopes and fears is a social evil which no one can defend. It is a cruel fraud to offer secret remedies claiming to cure diseases like cancer or tuberculosis which, so far as is known, are incurable by drug therapy. As reported in another column, the Minister of Health gave a sympathetic answer last week to a request for legislation to control the advertisement of medicines and surgical appliances. He had been interviewed by a deputation representing not merely the medical and pharmaceutical professions but also the advertising business and the newspapers as well as local authorities and other bodies with wide interests. The deputation was able to tell the Minister that a draft Bill had been prepared with a degree of agreement never previously attained. Its limited objectives were twofold—first the prohibition of advertisements of medicines, appliances, or treatments claiming to cure or prevent certain scheduled diseases, and, secondly, the prohibition of invitations to the public to obtain diagnosis or treatment of those diseases by correspondence. The specified diseases are those which are either incurable or are obviously unsuitable for unskilled treatment, and those sexual ailments which notoriously give a sinister opportunity to the impostor and the blackmailer. The Minister agreed that legislation was needed, but he naturally added the inevitable reservations about the existing commitments of the Government's programme which must be expected from responsible members of the Cabinet. We would venture nevertheless to beg the Minister to remind his colleagues, whatever their political preoccupations, that the existence of this public scandal is no new discovery. It is now over twenty years since a Select Committee of the House of Commons was appointed to inquire into the sale of proprietary remedies. The resultant report (reprinted as a special supplement to THE LANCET of Jan. 10th, 1925) was as damning a document as could be. Even if the evidence whereon its conclusions were founded belongs to the pre-war period, those conclusions might equally be reached after inquiry to-day. While the Select Committee found that patent and proprietary medicines were in some cases genuine scientific preparations or unobjectionable specifics for simple ailments, it declared that many secret remedies made grossly exaggerated claims, caused injury by delaying recourse to proper medical treatment, contained large quantities of alcohol in disguise, were sold for improper purposes, and professed to cure diseases incurable by medication. Some were "essentially and deliberately fraudulent," marketed by swindlers who exploited for their own profit the apparently invincible credulity of the public. Well might the Select Committee describe all this as a grave and widespread public evil. New legislation, it observed, was urgently needed; the existing law was chaotic and had proved inoperative; prosecution for fraud was hampered by the greatest difficulties, and the sale and advertisement of secret remedies went on practically uncontrolled. Foreign countries and the Dominions oversea managed to protect their citizens; in Britain the law was powerless. And this indictment has been left on the file for over twenty years.

Since 1914 Parliament has enacted useful reforms in kindred matters. The traffic in dangerous drugs has been restricted; the standardisation of therapeutic substances has been secured, and the laws of pharmacy and poisons have (quite recently) been overhauled. But the Proprietary Medicines Bill, officially designed to give effect to the main recommendations of the Select Committee, though introduced in the House of Lords in 1920, was allowed to die quietly and still awaits its resurrection. When the Food and Drugs (Adulteration) Act of 1928 rewrote the familiar prohibitions on sales to the prejudice of the purchaser, the old exception in favour of patent and proprietary medicines was preserved. The Merchandise Marks Act penalises the sale of goods under a false trade description. In the main, however, the buyer is left to such redress as the common law affords him. Criminal proceedings for fraud break down for three simple reasons. First, in serious cases, as where drugs have been advertised to procure abortion, the police can hardly produce a witness to proclaim the illicit purpose of her purchase and her disappointment at its results. Secondly, the defendant often manages to call somebody who says the secret remedy has really done him good; thus a few dubious testimonials excuse a thousand other cases of sheer imposture. Thirdly, it is impossible to prove wilful misstatement and guilty knowledge where retailers are ignorant, as they usually are, of the composition of what they sell. A case at Liverpool in 1907 struck the Select Committee as typical. The label on a preparation (which was sold for 2*s.* 9*d.* though its materials cost about a penny) stated that it contained "the active ingredients and digestive qualities of the gastric juice in a highly concentrated and permanent form." The analyst's certificate showed water, traces of phosphoric acid, hydrochloric acid, nitric acid, and calcium phosphate, flavoured with chloroform and a vegetable bitter, and coloured with cochineal. The minute quantity of hydrochloric acid was the only conceivable part which resembled the gastric juice. The retailers, not the manufacturers, of the remedy were prosecuted by the Liverpool Corporation. As it was not possible to prove their guilty knowledge, the prosecution was withdrawn, the defendants being awarded five guineas costs. It need scarcely be added that the City of Liverpool was thus discouraged from any similar action in the future. The Select Committee mentioned one other instance of the comparative impotence of our law. It was informed that an American called MACAURA had netted £60,000 by a campaign in England of advertising, exhibiting, and selling an alleged vibratory cure for many ailments, whereas for the same procedure in Paris he was promptly sentenced to three years' imprisonment and a fine.

The financial success of secret remedies was part of the evidence which convinced the Select Committee that the evil was widespread. It noted that the owner of "Dr. Williams' Pink Pills for Pale People" left a fortune of over a million pounds. Companies which make and sell proprietary medicines have flourishing balance sheets. Their main expenditure is in advertisement, and in this imperfect human world this outlay gives them no small influence over the press. The Proprietary Articles section of the London Chamber of Commerce estimated in 1914 that two millions were spent annually in this country in advertising proprietary medicines. The Select Committee observed that this expenditure led newspapers, either from discretion or under compulsion, to exclude the criticism or discussion of secret remedies. When the British Medical Association sought to educate the public by issuing its volume on "Secret Remedies," most newspapers (according to the Committee's report) omitted to give it any editorial notice; many journals, even those of the highest class, declined an advertisement of the book. There are newspapers which exercise a vigilant censorship over the advertisements of secret remedies; there are others which do not. Even the medical papers, remarked the Committee, have not been scrupulously careful—just as, in another sphere where laxity is unfortunate, members of the medical profession have not always refrained from giving testimonials to dubious preparations. It would be foolish now to dissipate energy or to weaken the common purpose by scolding one another. What is wanted is a better law more vigorously administered. The Committee placed on record instances of exaggerated claims which all can condemn. Here are two taken at random. Vitadatio "will cure the most severe cases of cancerous growths, tuberculosis, consumption, heart trouble, and tumours"; the Government chemist found it to be apparently a decoction of bitter herbs containing only 1·48 per cent. of total solids and no alkaloids or resins. Antipon, "one of the most valuable discoveries in modern therapeutics, solving once and for all the vexed question of the radical cure of obesity without harmful after-effects," was found to be a solution of citric acid in water, without medical effect upon corpulency. This latter example may be paralleled from the last annual report of the Ministry of Health which mentioned certain "slimming tablets" as consisting of a mixture of aperient drugs likely to cause chronic purging. The salesmanship of the advertisers moves with the times. "Mother Seigel's Syrup," for instance, no longer bears the romantic statement that "an old woman, Mother Seigel, on her last legs with dyspepsia, was given up by her relatives and was allowed to wander in the lanes round her native village in Germany," where "one day she chewed a leaf of a herb, only found in those parts, and found immediate relief." The Select Committee opines that there was no such Mother Seigel and no such herb. The preparation, containing hydrochloric acid and borax, has been put forward as a cure for dyspepsia, liver complaints, and anæmia. It cannot be sold, unless smuggled, in Germany (where it is prohibited by name except on a doctor's prescription), France, Austria, or Italy. Britain alone enjoys this freedom. To fictitious names like "Mother Seigel" the Committee added evidence of other aids to success. It investigated an advertisement which read: "Fits—Clergyman offers prescription for 1*s.* 1*d.*—never fails." Application brought a prescription for "Koronium bromide" and a reference to the "actual manufacturers" in Cheshire. This was an invented name for strontium bromide, often prescribed for epilepsy, and purchasable, according to the Committee, at rates varying from 2*s.* to 3*s.* 8*d.* per pound. The Cheshire manufacturers sold it at 4*s.* 6*d.* for four ounces. The police found that the advertiser traded from a lock-up shop under the name of "Whitby and Co., chemists, opticians, and wine merchants." It will hardly be expected that the owners of secret remedies will place at the disposal of the public any new drug or new method of compounding known drugs. When the Committee looked into the less reputable concerns, it found proprietors whose commercial operations involved several aliases. Thus two Americans, VIRGIL P. NEALE and THOMAS ADKIN, were the Cartilage Company advertising a means of increasing height; as HARRIET META they sold a wrinkle eradicator; as KATHRYN B. FIRMIN, of the Roman Solvene Laboratory, they undertook to remove superfluous hair, and as EVERETT WOOD they offered to restore the hair to bald heads. Among other minor influences for misleading the public the Committee noted that the patent medicine stamp has been used as if it implied a Government guarantee. But the ridiculous anomalies of the Stamp Act deserve a chapter to themselves. Comic relief is rare in the statute book; no other country could produce such an example as the unrepealed schedule to 52 Geo. III. c. 150 with its list of drugs from "ADDISON's re-animating European balsam" to "ZIMMERMAN's stimulating fluid."

There is much to be said for the proposal that all remedies should exhibit their formula. An inventor has to disclose his secret to the Patent Office as a condition of protection. Why should the inventor of a medical preparation object to disclosure? The Select Committee, however, deprecated compulsory exhibition of formulæ except in the case of alcohol, poisons, and other dangerous drugs. A technical statement of constituent chemicals, it said, would convey little to the public. Disclosure would invite unfair competition and ruin the investments of existing shareholders. The Committee nevertheless recommended that the formulæ of all secret remedies should be compulsorily communicated in confidence to a competent official appointed under authority of a Government department. This proposal formed part of the Bill of 1920. There was to be official registration of all proprietary medicines and proprietary surgical appliances as a condition precedent to manufacture or sale. Though the draft Bill which was mentioned to the Minister of Health last week has not yet been published, it is understood that it does not go so far as the Bill of 1920. For the present we must concentrate on a reform of the law which is practicable; it is imprudent to imperil the measure of agreement already attained or to antagonise vested interests unnecessarily. The draft Bill will be welcomed by the proprietors alike of respectable newspapers and of respectable remedies. The attitude of the medical profession will not be in doubt, although, needless to say, the proposals are not put forward in the interests of surgeon or physician but in the public interest. If the public is allowed to know the evils of the present system, the public will demand the reform. Nor will it wish to wait another twenty years.

GOLD AS A REMEDY

THE history of the gold treatment of pulmonary tuberculosis is well known. KOCH's observation that potassium gold cyanide kills tubercle bacilli in vitro, though later shown to be irrelevant, is an impressive starting-point. FELDT's compounds, aurocantan and krysolgan, were produced about the war period and attracted less attention in this country than MØLLGAARD's sanocrysin in 1924. After the first wave of enthusiastic interest had passed, sanocrysin settled into a modest but significant rôle in the treatment of phthisis: clinical opinion, in this country at least, holds it capable of checking the destructive process in the lung in certain phases of the disease, but its effect is not predominant among the influences that determine the patient's course, and therefore, in series of cases such as the one reported by Dr. PETERS and Dr. SHORT in our last issue, its use may bring no amelioration of the death-rate.

Meanwhile other gold compounds have been made by the chemists and other fields of possible usefulness explored by the clinicians. Gold treatment of chronic arthritis began on the continent several years ago and is now attracting more notice here. Two months ago we published a report[1] from Liverpool that dealt with 100 cases of rheumatoid arthritis, osteo-arthritis, and "menopausal arthritis": every patient received one course (occasionally more) of gold injections, in addition to routine dietetic and physical treatment, and five years after the series began Dr. PEMBERTON was able to classify 50 of them as cured or very much improved, and a further 38 as improved. And last week, another group of 100 cases[2] was reported by Dr. HARTFALL and Dr. GARLAND from Leeds. Although observed only in the past two years, these cases provided in some ways a more striking result, for physiotherapy and analgesics were withheld and gold was in effect the sole treatment. The arthritis was always of the rheumatoid type, its average duration was several years, and more than half the patients had previously had various kinds of treatment without lasting benefit. Gold was given intravenously, in small to medium doses, but the injection courses were repeated, with intervals of at least six weeks, two or three times or more. HARTFALL and GARLAND claim cure or marked improvement in 70 per cent. of the cases, but rightly point out that the method is still in an experimental stage, and much may yet be learned about optimum dosage and other therapeutic details. Gold has also been tried in syphilis, leprosy, actinomycosis, and other chronic inflammatory and granulomatous conditions, as well as in dermatology; in Germany it has been warmly advocated for asthma, "especially in cases where modern psychological treatment is unavailing"[3]—a claim supported by Dr. SOBHY's letter in our issue of August 11th, 1934, and by Dr. BANSZKY in a note appearing on p. 79 of this issue.

Trial and error is the only method by which the value of gold as a remedy will be defined, and more trial is still necessary. The error, unfortunately, involves disasters as well as failures. Moderate reactions, in the form of fever, albuminuria, vomiting and diarrhœa, and erythematous skin rashes, are familiar to all who have used it. A severe exfoliative dermatitis occasionally occurs, and it is now being realised that fatal damage to the blood-forming organs can be caused by gold. The Leeds report already mentioned included two deaths from thrombocytopenic purpura, and a third non-fatal case is reported by Dr. HUDSON in our present issue. Almost nothing is known of the mechanism whereby gold acts, either beneficially or harmfully, and the harmful effects recorded seem to bear little relation to the preparation or the dose used. There is some evidence that severe purpuric reactions can be successfully combated by blood transfusion, and in Germany calcium administration is thought to protect to some extent against all toxic effects. Gold remains, however, a two-edged weapon, brandished in the dark. If, in such serious diseases as rheumatoid arthritis, it does good that nothing else will do, then a certain risk of harm can be justified. At the present stage in its history, it should clearly be used and investigated by experienced workers, who have groups of suitable cases under their control, and who are on their guard against its dangers; it is not a remedy for the therapeutic dilettante.

HOSPITALS LARGE AND SMALL

THERE are now in London 145 voluntary hospitals which keep their accounts according to a uniform pattern[1] and submit these annually for publication as a condition of the support of King Edward's Hospital Fund. This fund compiles and issues separately every year: (1) a statistical summary of the income, expenditure, work, and costs of these hospitals; and (2) a statistical review of the total figures. The summary for 1934, just issued,[2] costs only a shilling, and contains a mass of information so aptly grouped and attractively presented that even those with no direct concern in hospital administration will find in it material of interest. The annual budget of all the hospitals combined, covering nearly 15,000 occupied beds and 10 million out-patient attendances, was in 1934 not far short of four million pounds. Those who cling firmly to the voluntary principle of making provision for the sick poor will be gratified to learn that 91 hospitals had a surplus, and only 54 a deficit, of income over expenditure during the year and that there was a net surplus for all the hospitals in 1934 of £93,000, or 2·4 per cent. of the total general expenditure. Perhaps the two most interesting items about each hospital from a broad point of view are (*a*) the percentage of the average bed complement which is vacant and (*b*) the annual cost per occupied bed. It is satisfactory to be assured in the prefatory note that the lowest cost per occupied bed is not intended to be taken as a model. All comparisons are with the average and even so, high cost is not necessarily interpreted as implying excessive or extravagant expenditure. It may of course mean relatively inefficient administration; but it may also mean a higher standard of diagnosis or treatment, or of general comfort than that deemed adequate in the average hospital of the same size or kind. For example, in some of the hospitals the establishment and maintenance of a bigger staff of trained nurses or of domestic help to relieve nurses for more important duties, or the provision of additional comforts for patients, are cited as causes of increase in the cost per occupied bed, which can be fully justified; similarly among the smaller hospitals the enlightened boards of management who are prepared to bear the overhead charges associated with radiology and pathology departments offer diagnostic advantages to the patients which are clearly worth while. The variation in the cost per occupied bed is enormous—from £71 at a heart hospital for invalid children to £339·8 at a hospital for Anglican clergy and their families. The average for all hospitals is £174·7, and it is of interest that of the 16 groups into which the 145 hospitals are classified the only ones which show a total cost per occupied bed above this average are Group I, the 12 general hospitals with medical schools covering 6000 beds (£203·2) and Group XI, the 9 maternity hospitals covering 600 beds (£176·9), the average percentage of available beds which are vacant being in each group approximately 11. Of the 10 small hospitals in Group VII (general and cottage hospitals under 40 beds, without a resident medical officer) which are often regarded as being relatively expensive to run, the cost per occupied bed in 9 instances is under the average for all hospitals; the exception has had more than 10 of its 18 open beds (58·7 per cent.) vacant during the year, and it is therefore less surprising that its cost per occupied bed should be £264·6. The only hospital averaging a still larger percentage of vacant beds is one of the smaller maternity hospitals, at which 65·4 per cent. of the 50 beds were generally unoccupied.

The question immediately arises whether hospitals with so many vacant beds are really filling a need which justifies their existence and are thus worthy of support, or whether they are only deflecting money and philanthropic effort which might more profitably be used elsewhere. This is not a problem of only local interest. There must be many hospitals outside as well as within the London area to which it applies. Recently we were asked by a correspondent whether there is justification for keeping open a cottage hospital of 30 beds in a district which could be served by another much larger and better equipped hospital. The annual income of the cottage hospital in question is £4000 and its expenditure £5000, and the struggle to keep it alive is arduous. Is it worth it? The question can certainly not be decided in the abstract, without a study of the conditions and needs and population of the district. The smaller general hospitals and cottage hospitals are often centres of local interest and local patriotism. It is a joy to many in the neighbourhood to work in and for these institutions and to contribute to their upkeep. In some places where a local hospital is successfully conducted it becomes almost a social centre. From the patients' point of view, moreover, it is always regarded as preferable to go to hospitals where they know the doctors in attendance, and where they can be easily visited by their relations and friends. The fact that the standard of work may be less high than in larger centres with many special departments is not appreciated by them. Local hospitals are, of course, of undoubted advantage to the general practitioners of the district, because the doctor is able to follow his patient into hospital and perhaps to continue in charge of his patient, or at any rate to discuss the case personally with the consultant, a discussion which may have high educative value. From a financial point of view, again, experience has shown that the closure of one hospital and the enlargement of another to take its beds is to reduce the combined income. There is, however, a real requirement for tabulation and analysis of the hospital facilities all over the country in terms of the needs of the population in the area. Such a survey was made for London in 1933, when the London Voluntary Hospitals Committee, in conjunction with the central public health committee of the L.C.C., carried out an exhaustive survey of the hospital accommodation available for those who live in the county.[3] The information collected was set out in detailed tables showing the number of beds in each hospital within the area and the use to which these beds are put; these tables included a statement of both in-patient and out-patient work at the several hospitals. The geographical relation of the hospitals to one another was graphically shown on two large-scale maps which were reprinted in reduced form and circulated with the report. A corresponding survey of hospital accommodation throughout the country would show the geographical relation of the smaller general and special hospitals to the larger and more centrally placed ones, and also the relation of the various hospitals to the density of population. The information thus provided would show up areas where increased accommodation is likely to be needed, or it might supply at a glance good reason why a certain hospital has an undue proportion of its beds unoccupied. Such a survey should include reports from authorised visitors of work done in the hospitals situated in each area and a statistical summary corresponding to the one for London to which we have referred above. If information were published on these lines, those hospitals which clearly fall below the average level in efficiency of administration and work done would have a great incentive to improvement. It is by no means clear that a survey would reveal that even quite small hospitals could be spared or that the present tendency towards centralisation in hospital affairs is likely to increase. Centralisation has many drawbacks, and the increasing speed and ease of making daily contact with scattered units may well produce a reaction in their favour.

[2] Obtainable from King Edward's Hospital Fund for London, 10, Old Jewry, London, E.C.2. Pp. 100. 1s.

If the local authorities and voluntary hospitals could be persuaded to collaborate in a joint national survey of this kind there is one respect in which they might with advantage depart from the pattern of the summary issued by King Edward's Hospital Fund. There the statistical cost of an out-patients' department is based on its cost per 1000 attendances. It is clear that this method of reckoning costs is a direct encouragement to hospitals wishing to demonstrate efficient and economical administration to maintain or increase the number of their attendances. It is now generally admitted that a large proportion of the attendances represent work which could properly be done by general practitioners[4]; but hospital authorities are hardly likely to give ungrudging help in thinning their lists while the costs of their out-patient departments are reckoned and compared on the present basis.

ANNOTATIONS

SUICIDE

SUICIDE is so important a problem that its study from every angle should be encouraged. It is, however, desirable that the methods used in its investigation should be such as may throw further light on its causes and its prevention. To use clinical material in such a way as only to confirm what psychiatrists and sociologists already know of suicide is not to make the best use of it. These reflections are prompted by the study[1] published by Miss Stoneman, Ph.D., a psychologist who investigated the cases of attempted suicide admitted to a certain ward in the Royal Infirmary, Edinburgh, during the years 1932–1933. This work is a good example of the kind of painstaking inquiry that fails through unsuitable choice of material and method. The author's procedure was in the main the psychiatric one of inquiry into the history of each patient and into the background of the immediate situation. Motives were discussed with the patient at length, psychological tests were given, and in themselves the case-studies are as complete as possible. From these studies, however, Dr. Stoneman draws some statistically unacceptable conclusions, to which she appends a new psychological theory to account for attempted suicide.

Suicide is, in fact, here investigated as a problem in itself. But suicide is only a problem in itself if one eliminates all that persons who attempt it have in common with those who do not. Many depressive patients, for example, never attempt suicide; it would be useless to look in them for the causes of suicide though one might well look for the causes of depression. But if one who examined depressive suicides might discover only the causes of their depression, he would not have advanced his knowledge of the causes of suicide in depressive persons. The same may be said of the many other people who attempt suicide; to investigate them without control material may throw light on many things but miss the essential point under consideration. Dr. Stoneman's notes of 87 patients reveal, for example, that distress, whether occasioned from without or from within, is the commonest state before suicide. She finds in these cases adverse social forces, adverse individual endowment, drunkenness, disease, thwarted desires, and the other causes of unhappiness or of an unbalanced attitude towards life and death. But this adds nothing to our knowledge. It is true that hardly any people commit suicide when they are happy, and that the causes of unhappiness are in some measure the causes of suicide. But suicide cannot effectively be studied without regard to the different kinds of disturbance of mind and adaptation in which it occurs. There may be little in common as regards causation and prevention between the hysteric who dramatically takes poison, the hapless lovers who decide to die together, the melancholic who cuts his throat, the fanatic, the martyr, and others of the great army of suicides. Nor can unsuccessful suicides be taken as representatives of suicides in general. Among them may be many who have not made a genuine attempt to kill themselves at all. Conclusions drawn from them may show why apparent suicidal attempts fail or what determines the choice of an ineffectual method, but not necessarily much about the cause of the attempt; in studying these cases one is after all studying "suicide" that is not suicide in act, whatever one may suppose it to have been in intention. If suicide is to be investigated as a single specific problem, somewhat rigid statistical methods are required, because there are so many variables. Such studies as those of Donalies in Berlin, and Lendrum in Detroit upon unsuccessful suicide, and the wide surveys of Dublin and Bunzel, Loewenberg and many others show what constant findings a careful statistical treatment yields.

[1] Halfway to the Hereafter. An Enquiry into the Motivation of Attempted Suicide. By Ethel Turner Stoneman, B.A., A.M., Ph.D. Perth, Western Australia: T. F. Christie. 1935. Pp. 96.

Studies of suicide as a particular aspect of depression or some other psychiatric syndrome, or as an expression of fear or hate or death-instinct, according to this or that psychological theory have of course their place, though often they are either too general or too conjectural. The psychological approach must leave unanswered many social and biological problems that are of the first consequence in prophylaxis, and it is possible that at this stage sociological inquiries are likely to be more fruitful than are further psychiatric ones. We know that such things as economic hardship or the "featuring" of suicides in the press contribute to a rise in the suicide rate; but we can do little as yet to influence these. We know that competent psychiatric diagnosis and treatment can often avert suicide, but we cannot always prevail against public prejudice in regard to such treatment, especially if it is to be in an institution; and at the moment concentration on propaganda for mental hygiene and improvement of social condition is needed more than inquiry into the individual miseries which precede the decision to end life.

ERRORS DUE TO ANTICOAGULANTS

THE possibility that the anticoagulants in general use may cause errors in blood analyses has been suspected for some time. I. Blitstein[1] has now made a careful study of the variations which may be produced in this way. He has investigated the influence of potassium oxalate, sodium citrate, sodium fluoride, zinc sulphate, heparin, hirudin, and a proprietary anticoagulant called Liquoïde (sodium polyanethylsulphonate) on the following estimations: inorganic phosphorus, plasma proteins, chlorides, cholesterol, dry extract, and hæmatocrit. There are, he finds, two sources of error. First, the plasma becomes more dilute owing to water leaving the erythrocytes; this is dependent upon the increase in ionic concentration of the plasma due to the added anticoagulant. This effect is constant for the first four substances investigated and is in proportion to the quantity of the substance used. The second effect is more marked with fluoride and oxalate than with citrate and sulphate, and is due to the toxic action which these salts exert upon the envelope of the erythrocyte, whereby it loses the properties of a semi-permeable membrane and allows some of its contents to diffuse out into the plasma. The author concludes that these four anticoagulants should be discarded and that hirudin, heparin, or liquoïde be employed in estimations of hæmatocrit, dry extract, chlorides, and cholesterol. In determination of inorganic phosphorus, he holds, liquoïde only should be used as heparin contains traces of phosphorus and hirudin disturbs the colorimetric comparison. For plasma proteins, he believes that fibrinogen should be estimated by the refractometric method of W. Starlinger[2] and albumin and globulin from the serum. The interest in this paper lies in the conclusion that the anticoagulants in common use are those most apt to produce errors in estimations. Perhaps the point of greatest practical significance is that the hæmatocrit varies over a wide range with the four interdicted substances but is constant with the three others. The two blood analyses most helpful to clinicians—blood-sugar and blood-urea—have not been considered in this study.

THE ROYAL SURGICAL AID SOCIETY

THE annual report of the Royal Surgical Aid Society for this year has just appeared and the record of the work done shows that the society is living up to the high standard of practical utility which it has manifested since its start. And that is a considerable period, for it was established in 1862 at a time when no institution existed through which the needy patient could obtain much choice of the required surgical appliances. Many institutions did, and still do, largely assist discharged patients to obtain orthopædic appliances, this being particularly the case when an instrument of a certain sort was needed to maintain the improvement manifested and lead to further progress. But three-quarters of a century ago it was seen that such assistance was only applicable to the fringe of the manifest needs, and to-day, with the enormous growth of these needs, the value of the central organisation is more than ever obvious. The records in the annual report demonstrate how extensive and various are the wants of the applicants, and over 29,000 cases have had those wants supplied during the year under review. The charitable public has responded well throughout the history of the society, enabling it to continue its mission, but the committee appeal for more liberal support during the coming year, since there has been a slight falling off of income which does not accord with a certain abatement of general financial stringency. But while there has been a decrease in special donations in aid of cases, the payments received from patients themselves show a gratifying increase, while the cost of administration has remained almost stationary.

Accompanying the report there is an appeal for the constitution of a special fund to be devoted to the relief of cases in the Durham district. The demands from the distressed areas, Durham being taken as a centre, have increased to such an extent that the committee of the society do not feel justified in meeting them from the ordinary resources. There are, it seems, practically no subscribers to the society in the Durham district, and conditions being as they are it is obvious that assistance will have to be found from outside. Therefore the society is making a special appeal for the raising of a fund of at least £3000 in order to cope with this urgent situation, pointing out that if funds are forthcoming, enabling them to deal with the cases locally, a more direct control of the assistance will be created and trouble and postage saved on many fruitless applications by letter. Support in aid of this special appeal should be sent to the Royal Surgical Aid Society, Salisbury-square, London, E.C.

SYPHILUS AND SYPHILIS

IT is given to few men to achieve immortality by the expedient of inventing a single word. Such an unwonted survival has fallen to the lot of the poet-physician Fracastor, and in a fashion all the more curious because the fateful word occurs only in a somewhat uneasy addition to his poem as first written and finally taken as a part title for the extended work—*Syphilis sive Morbus Gallicus*. In this appended Book III, Fracastor relates how a certain shepherd, Syphilus by name, provoked Apollo by his impiety and as punishment was smitten by a new disease which from this the name of its first victim his fellow countrymen called "syphilis." In a recent issue of

[2] Biochem. Zeitschr., 1923, cxliii., 179.

Fracastor's poem[1] his elegant Latin hexameters are printed on one page, and on the opposing page an English translation. Although this follows the Latin text closely, there is nothing in the easy and polished English prose to indicate that it reproduces accurately an original in another tongue. Mr. Wynne-Finch wisely gives his explanatory matter in a series of scholarly and delightful appendices, and limits his footnotes to the minimum necessary to explain the text. Mr. J. Johnston Abraham's erudite but most interesting preface tells of Fracastor's life and work, explains the range and purport of this famous poem, and recounts the circumstances of the great epidemic of the Morbus Gallicus. He declares his adherence to the theory of the importation of syphilis from America, brushing aside with a somewhat peremptory gesture the arguments against this theory. The collaborators have done their work so well that the result should attract a circle of readers of very diverse tastes. The classical and historical matter will, of course, have a wide appeal, but even the reader who had at the best but small Latin, and that long since worn threadbare, will not find his interest flag.

THE GROWTH OF KING'S COLLEGE AND HOSPITAL

WHEN John Curnow died in the year 1902 he had written and published, in the annual *King's College Hospital Reports*, a history of the college and hospital to the year 1880. In his obituary notice in the Reports doubt was expressed that a successor would be found with knowledge sufficiently deep to carry the history further. Fortunately however such a one has emerged in Willoughby Lyle, who has not only carried the unfinished task to 1934 but has rewritten and amplified the account of the early years.[2] Having been dean of the medical school for over 20 years, at a critical period in the hospital's existence, Lyle was well equipped for the task; but without his zeal, energy, and love for his school we should not have had such an interesting record of its 103 years' existence, or such a vivid and truthful description of its teachers and students. Not to King's men alone will this history appeal. Amongst the facts and events are many of wide and general interest.

The work begins with an account of the foundation of King's College and the medical department (1831–39) and there follows a description of the period of the first King's College Hospital (1839–61). This was the renovated workhouse of St. Clement Danes, in Portugal-street. The second King's College Hospital was built on an extended site of the first. It was opened in 1861, cost about £100,000 and had accommodation for upwards of 200 beds. The record of this second King's College Hospital is divided into the period before the advent of Lister (1861–77), the Listerian period (1877–1893), and the period subsequent thereto (1893–1913). The third King's College Hospital was opened at Denmark Hill on July 26th, 1913, by the King. It was designed when finished for 600 beds, and was admittedly, at the time, the last word in hospital construction. Within a year of the admission of patients the war broke out, and a large part of the new building became the Fourth London General Hospital (R.A.M.C.T.). After the war reorganisation became imperative; several new departments were created, promotions and new appointments were made, and the foundation was laid for the present excellent system of teaching. In the course of each section Lyle gives a chronological account of all important events, and a "medical history" of the representative King's men of the period. These personal records contain many interesting anecdotes. A short section deals with the interchange of teachers between King's and other metropolitan medical schools. An account is given of the establishment and progress of the Clubs and Societies Union. Though several inter-hospital athletic cups have been won, King's has never obtained the inter-hospitals rugby football or hockey cups. As an indication of the standard of medical work it is pointed out that the students have gained 108 gold medals at the university of London in the past 100 years. Tribute is paid to the second Viscount Hambleden, as a "public-spirited unselfish gentleman" who has been the hospital's greatest benefactor. This account of "King's" furnishes a valuable record of its development from being the mere department of a College (1830–1909) to the independent position of one of the constituent medical schools of the university of London.

FOOD POISONING

INVESTIGATING an outbreak of food poisoning is as fascinating and difficult a task as investigating a crime. In both the time factor is all-important; statements must be taken and clues examined before the passage of time blurs or destroys them. In both the coöperation of a number of experts and of the general public is necessary for success, and in both there is a central authority—the Ministry of Health or Scotland Yard—ready and eager to assist. Finally in both situations the investigation must proceed according to an orderly plan of campaign, and for food poisoning the Ministry have recently issued[1] what may be called a strategical plan, with notes on tactics, which every medical officer of health would do well to keep by him and use as a basis for any investigations he may have to make. The memorandum is a revised version of one issued in 1921, with an additional appendix giving technical hints on the identification of the salmonella types, the latter following the lines of the suggestions in the annual report of the chief medical officer of the Ministry of Health for 1933. It is to be noted that the specific duty is laid on the medical officer of health to report any serious outbreak of disease to the Ministry and also to furnish a copy of any special report which he may make to his authority, but otherwise he is free to carry out the inquiry on his own lines to and make use of local facilities for the bacteriological examinations if he so wishes. In outbreaks of food poisoning which are not of bacterial origin, the specimens will usually be sent to the public analyst appointed by the local authority; but in bacterial cases the chemical determination of the presence of "ptomaines"—in the sense of alkaloidal substances produced by bacterial action in meat foods—is held to be of no value. The memorandum also contains practical instructions for the collection, packing, and transmission of material, and suggests that the bacteriologist should always be consulted as to which specimens will be most instructive.

The incidence of food poisoning is by no means negligible. Every year some 40 to 70 outbreaks are reported to the Ministry of Health and in 1933 there were 66 outbreaks so reported with 15 deaths in the salmonella group alone. Often the article of food cannot be proved guilty; the police (so to speak) suspect the criminal, but evidence is insufficient to bring home the crime. But in every case the authorities depend in the first place on the willing coöperation of the practitioner to bring his suspicions to the notice of the medical officer of health and to ensure that specimens are preserved pending his investigation.

FOOD ALLERGY AND DIGESTIBILITY

STRICTLY speaking, the term "food allergy" implies the entrance into the blood stream of an unchanged food protein absorbed from the intestine and escaping destruction in the liver. Such an occurrence, as Alvarez[1] points out, is more likely to bring about disturbances away from the intestinal tract (e.g. urticaria) than local digestive symptoms like colic, nausea, or diarrhœa. In actual practice, however, supposedly allergic disorders such as migraine, angioneurotic œdema, and urticaria are not very often traceable to food sensitisation; thus in Alvarez's cases of severe urticaria, seen at the Mayo Clinic, it seldom proved possible for him or for the patient to pin the blame on any food. Another difficulty is the fact that supersensitiveness to some foods is apparently intermittent, varying with exercise, climate, and especially with fatigue and nervous strain. Finally, one has to reckon with an immense variety of possible noxæ; and it is no advantage, from the patient's standpoint, that the commonest foods such as bread, milk, and eggs seem also to be the commonest offenders—not the more easily delectable delicacies such as strawberries, caviare, or paté de foie gras. Alvarez and Hinshaw make the interesting suggestion that much of the digestive trouble caused by foods is due purely to irritation of the intestinal mucous membrane by the chemicals or cellulose they contain. On this view the "digestibility" of a food depends not upon its protein sensitisation action but upon some direct local effect, in the alimentary tract, of other substances besides proteins. Among 500 patients suffering (for the most part) from indigestion, Alvarez found that 7 per cent. were unable to drink milk because of severe distress; and 3 per cent. could not eat eggs, while many suffered after eating onions, apples, and cabbage. Chocolate, radishes, tomatoes, cucumbers, beef, coffee, lettuce, and many other foods were noted by patients as causative of indigestion. Such lists could of course be readily paralleled by many physicians, but extreme care is always necessary in drawing conclusions from patients' own deductions about their digestive capacities. Unfortunately Alvarez and Hinshaw's questionnaire gives no indication of the manner in which these various foods may cause their distressing effects, but their paper serves the valuable purpose of emphasising the importance of factors other than protein sensitisation in producing food indigestion. In our issue of June 29th Dr. W. C. D. Maile and Dr. K. J. L. Scott draw attention to the well-known effect of water taken with food in increasing the absorption of such a substance as sugar from the stomach, and to the fact that boiled milk is somewhat more rapidly emptied from the stomach than unboiled; and if such a relatively simple process as gastric emptying-time may be regarded as any indication of digestibility of foods it is evident that very small changes in the composition of a meal may produce quite obvious changes in "digestion." At the same time, minor psychic disturbances have so great an effect on gastric secretion and motility that all such observations have to be treated with reserve.

THE IRISH MEDICAL ASSOCIATION

AT its annual general meeting last week the Irish Medical Association gave approval unanimously to the proposal to amalgamate with the branches of the British Medical Association situated in the Irish Free State. For the last year and a half negotiations have been taking place between the representatives of the two associations and a draft agreement has been arrived at. This provides for the establishment of an autonomous Irish Free State Medical Union, consisting in the first instance of the members of the two existing associations who are resident in the jurisdiction of the Irish Free State. Members of the Union who leave the Irish Free State to reside in Great Britain will automatically become members of the British Medical Association, and members of the latter who go to reside in the Irish Free State will become members of the Union. From the point of view of the British Medical Association the Union will be regarded as a group of branches and will be represented by one member on the council of the Association. The Union will, however, be, as regards its work at home, completely autonomous, and will be responsible for its own government and by-laws. The members of the Union visiting London will be privileged to enjoy the amenities of the British Medical Association hours to use its library.

The Irish Medical Association has shown wisdom in deciding as it has. With a history of ninety-six years of useful work for the public and the profession to its credit a decision to merge its individuality in a newly formed organisation could not be undertaken lightly. It was clear, however, that the maintenance of two professional organisations in Ireland, engaged in almost identical work, was wasteful and cumbrous. Moreover, although there was cordial coöperation between the two bodies, neither could claim the prestige, influence, or authority that goes of right to a single representative organisation. It is designed that the amalgamation of the two associations should lead to members of the profession who have hitherto been unattached now giving their adherence to the Union. There are between two and three thousand medical men practising in the Irish Free State, of whom probably about one-third are members of one or both of the existing organisations.

LIVERPOOL VOLUNTARY HOSPITALS.—The report of the Commission which recently investigated the position of the voluntary hospitals of Liverpool has led to the establishment of a Liverpool Voluntary Hospitals Board, which has now had its first meeting. The eleven members include Prof. Henry Cohen, F.R.C.P., Mr. C. A. Wells, F.R.C.S., Mr. J. Bagot Oldham, F.R.C.S., and Prof. R. E. Kelly, F.R.C.S. The board is to investigate the proposals of the Commission and advise the nine teaching hospitals of Liverpool on their problems; it is also authorised to negotiate with the municipal authorities. The Commission took the view that the governing bodies of the four general hospitals must be amalgamated.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LX.—PROGNOSIS IN ACUTE EMPYEMA

THE considerations which influence the prognosis in acute empyema are numerous, as might be expected in a disease presenting so many different types; the causative organism, the age of the patient, the nature of the pus, and position and extent of involvement of the pleura are all important. Again, empyema is peculiarly liable to complications, both local and in other parts of the body, and delay in diagnosis, which is often obscure, and the particular methods of treatment employed have considerable influence. Recovery is often so complete that no permanent effects follow, and naturally this is more likely in the less extensive and more rapidly cured cases. A large proportion, however, must be expected to have lasting effects of greater or less severity, such as flattening or lack of development of the affected side of the chest, scoliosis, pleural adhesions, and thickened pleura.

Empyema may cause death by compression of the heart and lungs, pulmonary or cerebral embolus, pericarditis, peritonitis, cerebral abscess, septicæmia, pyæmic infections of bones or joints, toxic exhaustion, or rupture into a bronchus.

Causative organism.—The streptococcus is responsible for the most dangerous cases, and infection of the pleura by this organism may follow pneumonia or broncho-pneumonia, particularly of the type complicating influenza, or may be part of a blood-stream infection from tonsillitis, osteomyelitis, or the like. A specially fatal form is met with after measles or broncho-pneumonia following measles, and such cases rarely recover. Pneumococcal empyema, on the other hand, is far less serious, whether it follows pneumonia or is a primary infection; the patients are not as a rule very toxæmic, and any severity of symptoms is largely due to the mechanical effects of an exceptionally large collection of pus. Owing to the thick consistency of the pus and the large lymph deposits drainage is necessary, and the chief danger of this form of empyema is avoided if secondary streptococcal infection is prevented.

Age.—In infants under two years acute *streptococcal* empyema is a fairly common complication of broncho-pneumonia and has a high mortality, however carefully the case is dealt with. *Pneumococcal* empyema is, of course, very often met with in children. In the first three months or so of life the disease has a high death-rate; after this age, even in babies of less than a year, the results have been much improved by valvular methods of drainage and the exclusion of secondary infection; in these days the mortality from pneumococcal empyema should be under 5 per cent. This is a great advance on the time when open drainage was practised and caused collapse of the lung and a sucking wound of the pleura, so frequently to become infected with streptococci after a few days as the result of inspiratory aspiration while the dressings were being changed.

Adults are better able even in such conditions to resist the secondary infection; in a large proportion of adults the empyema is localised, so that even open drainage is not followed by bad results. In old age, however, the prognosis is disproportionately bad, for old people put up a poor fight against infections wherever they occur, and empyema is not uncommonly the result of a lung abscess or gangrene, conditions in themselves very dangerous and usually implying a mixed infection from the beginning.

Type of operation.—An operation which provides "closed" or valvular drainage has considerably modified the outlook, especially in pure pneumococcal cases, for it allows the escape of pus while at the same time preventing regurgitation and secondary contamination through the wound; also the lung is encouraged to expand early and become adherent to the chest wall so that the empyema is soon localised to the region immediately about the tube. Such valvular operations even give a higher rate of recovery in streptococcal and putrid types, though in these infection of the chest wall, often spreading cellulitis or erysipelas, is commonly met with and cannot certainly be prevented.

The closed methods, involving a small intercostal incision and the use of a catheter or other small valvular tube, I do not regard very favourably, particularly because of the liability to interruption of the drainage by plugs of lymph. The operation that I have for many years found the most satisfactory is to resect three inches of rib and sew in a thick-walled rubber tube with a diameter the width of the rib resected; skin and muscles are sutured around this tube with drainage of these planes in all but pure pneumococcal cases; the tube is prolonged distally by collapsible Paul's tubing which closes during inspiration and allows exit only of the discharge. The best drainage and most rapid healing are obtained by resection of the eighth rib some two inches in front of the inferior angle of the scapula; this region is also the most suitable for aspiration of generalised empyema. Where drainage has been established here, healing usually follows rapidly after removal of the tube on the tenth day. Necrosis of the cut ends of the rib is a very rare occurrence, though it is often suggested as the cause of delay in healing; a far more common cause of persistent discharge is the formation of a bridge of bone between the cut ends, so that the track is partially or completely surrounded by a bony ring which impedes drainage.

ASPIRATIONS—DRAINAGE

In suitable cases repeated *aspirations* have done much to diminish mortality, especially in streptococcal and post-influenzal cases, in "putrid" empyema or where the infection is from the beginning a mixed one, and in pyopneumothorax. During active pneumonia operation should not be performed, but the case should be tided over by aspiration. If the general condition does not deteriorate aspiration may be repeated daily until the empyema has become at any rate partially localised or the discharge has become thick; but when in spite of aspiration the temperature rises to a high level at night and toxæmia is severe, especially with a steadily rising pulse-rate, valvular drainage must not be delayed.

As a general rule, collections of thin pus may be aspirated and drainage is indicated when the pus is milky. When on repeated aspirations the fluid rapidly reaccumulates in large amount, and instead of gradually changing to thick pus it remains thin, the prognosis is bad and failure of eventual recovery is to be feared.

In nearly all cases *drainage* is in the last stage necessary to finish off the remaining localised abscess and minimise pleural adhesion. A small empyema may become cured spontaneously by inspissation of its contents or by evacuation through a bronchial fistula; even large ones have in exceptional cases undergone spontaneous cure by becoming encapsulated by fibrous tissue or by rupturing through the chest wall or into a bronchus; but for practical purposes such phenomena are unimportant, for nearly all cases will die unless surgical treatment is adopted. In pneumococcal empyema, even though generalised, early drainage seems to give the best results, but one aspiration on the day before operation temporarily improves the patient's condition and lessens the severity of the operation.

DOUBLE EMPYEMA—THE ANÆSTHETIC

Double empyema is naturally more serious than single, and has a correspondingly high mortality; fortunately the condition is not often met with. Drainage of both sides at the same time should never be done. Successful results have been obtained by establishing valvular drainage on one side and daily aspirating the other until the empyema operated upon has become localised; the second side has then been submitted to valvular drainage about four days after the first operation.

The *anæsthetic* is important, and in adults the outlook is improved by avoiding the use of a general anæsthetic. It is a simple matter to infiltrate the skin and muscles with novocain and block three intercostal nerves near the angles of the ribs; such local analgesia is especially indicated for old people. In young children and certain other cases a general anæsthetic must be used and open ether is usually the most suitable. The patient should be placed in position for operation before the induction is commenced. Ether is well tolerated, even in the presence of bronchitis, and appears to be less irritating to bronchi and lungs than is chloroform; gas and gas-oxygen are unsuitable for cyanosed patients and are contra-indicated for empyema operations.

During operation on a generalised empyema the danger of sudden death from displacement of the heart and mediastinum is a real one; it is diminished by preliminary aspiration, and in other cases must be guarded against by keeping the pleural wound closed as much as possible by fingers and swabs to prevent sucking in of air.

LOCALISED EMPYEMA

Localised empyema occurs in four typical situations —i.e., (1) in contact with the lateral chest wall between it and the lung; (2) lower down between the lateral chest wall and the diaphragm; (3) posteriorly in the angle formed by the vertebral bodies and the posterior ends of the ribs; and (4) between the lobes of a lung. 1. The first type gives the best prognosis, for it can be drained at its centre so that the lung speedily expands to diminish the cavity, and final healing should be rapid. 2. In the low lateral type by the partial collapse of the lung and rise of the diaphragm the drainage track tends to become oblique and narrowed, so that a bottle-necked cavity is formed; this is one of the commonest causes of persistent sinus and calls for resection of a portion of the rib or ribs behind the opening so as to obtain more direct drainage. 3. In the dorsally placed type, after drainage a rigid-walled dead space is formed which is obliterated slowly and with difficulty and tends to form tracks extending up and down for some distance from the tube; such cavities must be drained with a large tube until lipiodol injections and X rays show that the cavity has contracted down to a small circular area immediately related to the tube; this can then be removed and rapid healing may be expected. 4. Interlobar empyema possesses special risks, and the prognosis must be more doubtful than in any of the other localised forms. Delay is apt to occur in diagnosis, with resulting increase of toxæmia; efficient drainage may be more difficult and there is liability to pocketing; and bronchial fistula is a fairly common complication. In all cases of doubt as to the advisability of final removal of the tube two considerations should be borne in mind, continuation of drainage is necessary as long as there is a large amount of thick discharge or if lipiodol shows a large cavity.

BRONCHIAL FISTULA

Bronchial fistula is a more frequent complication of acute empyema than is perhaps generally appreciated, and according to some authorities occurs in as many as 10 per cent. of all cases; it is more common in children than adults. Rarely does its occurrence allow sufficient drainage to produce a natural cure; on the contrary, it is often the cause of death from infection of the other lung, from the establishment of a pressure pneumothorax by the sucking of air into the pleural cavity in a valvular manner, or by the admission of secondary infection. When rupture into a bronchus occurs pneumothorax is the usual immediate result. Such rupture is often precipitated by the sudden change of pressure while an empyema is being aspirated.

Foul-smelling pus from an empyema indicates a mixed infection and is usally present if there has been a communication with a bronchus; in the absence of streptococci the foulness of the pus is not an indication of special severity.

SPECIAL ARTICLES

THE ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

THE ninety-fourth annual meeting of the Association took place at Chandos-street and the Westminster Guildhall on July 3rd, 4th and 5th, under the presidency of Dr. **REGINALD WORTH**, medical superintendent of Springfield Mental Hospital. Among the distinguished foreign guests were Prof. M. Laignel-Lavastine (Paris), Dr. Jacques de Busscher (Brussels), Dr. Robert Largeau (Paris), Dr. Jens Chr. Smith (Denmark), Prof. A. J. Westerman-Holstyn (Netherlands), and Prof. W. Mayer-Gross (Heidelberg).

The presidential address by Dr. Worth dealt with

Four Decades of Psychiatry

Dr. Worth paid a tribute to the broad-minded policy pursued by the Middlesex County Council in matters concerning the welfare and treatment of the mentally afflicted, and alluded to the new mental hospital at Shenley, which was visited by the Association on July 5th. After criticising a number of new methods and vaunted aids, he confessed himself as much bewildered now when confronted with a case of psychosis as he was at the outset of his career, largely because the causes have escaped recognition in spite of vigilance. He had much to say in condemnation of exhibitionism, loose talk, and pornographic potboilers, which he regarded as a feature of present-day life that must lead to a very undesirable state of society. Psycho-analysis was, he said, still very controversial, and acrimonious discussion on it had not been stilled. There were numerous temperamental differences in people, involving varying response to psycho-analytic theory, but he did not deny its capacity for the elucidation of mysterious ailments of the mind. By accepting some of its postulates one could determine a fairly definite mental pathology, such as the mechanism and mode of evolution of neurosis and psychosis. But the over-emphasis of sex had given definite offence to certain individuals. In recent years he had been much impressed by the increasing amount of adolescent psychosis, and asked whether this indicated that the present generation was breeding a greater number of psychopaths. In searching for hereditary factors, the figures were largely vitiated by the wide practice of family limitation. He was inclined to impeach the complications of modern life. The problems of mental involution would ultimately, he thought, be solved in the laboratory. Dr. Worth criticised the nomenclature of mental disease, and concluded by dealing with the chemical, biochemical, and physical aspects of insanity, expressing the belief that better histological methods and further research into structure and function must contribute vastly to the elucidation of the mysteries of mental disorder which, so far, had not been cleared up. There was on foot now, he said, a movement to oust the medical superintendent from his position of head of affairs in his own hospital, the suggestion arising to appoint lay directors or managers to mental hospitals, and a move was being made to deprive mental hospital visiting committees of their statutory powers. To these proposals he was strongly opposed.

The Dissertation Prize was awarded to Dr. A. GUIRDHAM, of Brentwood Mental Hospital.

Dr. THOMAS D. POWER read a paper on

Modern Endocrinology and Mental Disorder

He said that the more recent developments in endocrinology were of great interest to the psychiatrist. The pituitary gland, which was closely connected with the diencephalon, was found to exert a profound influence not only on the rate of bodily growth, but also upon sexual development and metabolism. It exercised most of those functions through the medium of other members of the endocrine group, while the latter, in their turn, had the power of influencing the pituitary. These relationships were very complicated and not yet understood. It seemed that one of the functions of the pituitary was to supplement certain forms of nervous activity by initiating a series of chemical changes in the body, and that, in this respect, it was subservient to the organic needs of instinct. Dr. Power described a number of investigations which he had carried out, and said it seemed probable that all instinctive and emotional activities were accompanied by subtle alterations in hormonal balance, and that those, in turn, influenced neuronic processes. The pituitary had some claim to be regarded as the master gland of the body. It was easy to imagine how a profound emotional disturbance could be perpetuated by endocrine disharmony, and so prove susceptible to substitution therapy. A combination of anterior pituitary hormones suitable for hypodermic injection appeared to be a desirable therapeutic agent, but, until such a preparation was placed on the market, workers in this field must content themselves with minor laboratory and clinical experiments.

Dr. F. L. GOLLA, Prof. LAIGNEL-LAVASTINE, Major J. E. DHUNJIBHOY, and Dr. DAVID SLIGHT (Montreal) discussed the paper.

Dr. H. C. BECCLE described some recent investigations into

The Hæmatology of the Psychoses

He said that much research had been carried out in recent years on the structure and function of the blood elements, with a view to ascertaining whether there were any regular quantitative and qualitative changes in the cells which would prove of diagnostic and prognostic value in disease, and, naturally, special attention had been devoted to the reaction, if any, of the reticulo-endothelial system to psychosis. This communication was concerned with certain changes in the neutrophilic polymorphonuclear leucocytes in disease, especially mental disease, to which he had been devoting attention at Springfield Mental Hospital for some time. With regard to the sudanophil granules, it was not yet definitely established whether they were manifestations of endogenous leucocyte damage, or were true inclusion substances resulting from phagocytosis of tissue cells. Jonescu had investigated 80 cases of various acute, subacute, and chronic diseases, and found that in a large proportion of his patients the number of granules of both varieties followed somewhat closely the course of the disease. That worker came to the conclusion that a quantitative estimation of sudanophil and toxic granules was of diagnostic import, and when made at intervals gave a useful prognostic indication. Dr. Beccle therefore thought such estimations might be of value also in the psychoses. It could be stated, in a general way, that the higher the granule count the more severe was the infection or disease. He described the technique he followed, and the frequency of the various examinations. In all, 20 acute and subacute cases were investigated; 15 normal people, including members of the nursing staff, were examined; and 10 chronic cases were also submitted to these tests. More cases, and especially more controls, were required to enable an assessment to be made of normal phasic events, but certain facts emerged from information already to hand. First, the toxic granules were found in much greater profusion than the sudanophilic bodies; secondly, while there was no close quantitative relationship between the two varieties of granules, there seemed to be a serial continuity between each series of estimations taken separately. Jonescu was definite in stating that sudanophil granules should never appear in the polymorphonuclear leucocytes under normal conditions; in his view they indicated chronic, possibly latent, infection. Dr. Beccle's own view was that a toxic granule count of 9 per cent. and a sudanophil count up to 5 per cent. could be regarded as normal.

In his group of 20 psychotic patients examined in the acute stages of their disorders, there was a fairly close relation between the intensity of the psychosis and the percentage of the sudanophil granules and the toxic granules, high figures indicating severe disability. Lower counts were associated with an abatement of acute symptoms. An instructive case was that of a female schizophrenic, of reaction type, aged 34. With the improvement in her mental condition the granule count fell from 74 and 46 to 32 and 4, these representing percentages of toxic and sudanophil bodies. There was also a moderately high sedimentation-rate and total white count, and there ensued a noticeable improvement here too. In a number of the cases he was not able to retain the patients long enough to make a proper investigation, but he felt able to draw certain conclusions. The toxic and sudanophil granule estimations appeared to follow the course of psychosis, varying directly with the intensity of the disorder. The gradual improvement in the counts observed in recovering cases must be ascribed, in part, to the general detoxication which was instituted in each patient soon after admission. It would be rash to infer, from the results of so few examinations, that these estimations had definite diagnostic and prognostic value, but he suggested that they might prove of considerable assistance. The paper was discussed by Dr. Rosa Stern, and Dr. Beccle replied.

Dr. W. D. Nicol read a paper contributed by himself and Dr. E. Lilian Hutton on

Clinical Aspects of General Paralysis of the Insane

They said that before the days of malaria therapy general paralysis was regarded as an incurable disease with a fatal termination within a few years of its recognition. Some said it was not new to witness remissions of the disease which were regarded as cures, while others declared that the occurrence of remissions falsified the diagnosis. Another group held that the disease had changed in character. A Board of Control inquiry showed that of 624 untreated general paralytics admitted to mental hospitals in 1923, 90 per cent. had died by the end of 1927, and Dr. E. T. Meagher, who made the inquiry, said that complete remission of a year's duration was very rare. As to a possible change in the character and severity of G.P.I., it seemed possible that the modern arsenical treatment of syphilis had modified the subsequent development of neurosyphilis. Many patients denied syphilitic infection, and so had had no antisyphilitic treatment. A further question was whether the diminished alcoholism of the present era had been a factor in altering the picture. It must not be forgotten that a Wassermann-positive cerebro-spinal fluid did not necessarily mean that the case was one of general paralysis. There were three clinical varieties in which the serological findings were positive: (1) the true general paralytic, whom it should be possible to diagnose without laboratory help; (2) doubtful cases, having one or two vague symptoms, in whom a positive Wassermann should indicate the possibility of G.P.I. and so of therapeutic measures; (3) those in whom, during routine examination, a positive serum was discovered. Kraepelin's description of G.P.I. was "a progressive deterioration leading to complete undermining of the whole mental and physical personality, accompanied by peculiar irritative and paralytic phenomena." To-day, however, the disease was no longer a fatal one; a certain percentage of cases treated by malaria recovered sufficiently to justify their discharge, while in others the progress of the disease was arrested.

This paper was based mainly on 100 consecutive admissions of each sex. In many cases preparetic symptoms passed unnoticed for long periods, and only when they were pronounced did relatives remember less marked symptoms some time earlier. Changes in character, irritability, outbursts of temper, apathy, or emotional instability were frequent, as well as a general falling off in efficiency. Either insomnia or excessive sleepiness might be present, and slurring of speech was a very valuable sign, often an early one. Depression preceding the development of grandiose ideas was often observed. The simple dementing form was characterised by a general mental deterioration, but this must be distinguished from the type of confused paretic. Sometimes the clinical picture of the simple dementing case was tinged with a strong grandiose or confused element, and false hopes of recovery might be held out because of the presence of the confused element. Slurring of speech occurred in 80 per cent. of women patients. Increased knee-jerks and the Argyll Robertson pupil were present in about half the cases. The concurrence of tabes with G.P.I. was present in 5 women, and 6 men. Seizures very rarely occurred in the pure grandiose or confused types; they were most frequent in the simple dementing type, and were generally followed by some dementia; 23 men and 30 women had seizures. These cases with seizures were less likely than others to benefit from malaria therapy, and the seizures influenced the prognosis adversely. In 220 cases of each sex there was no patient younger than 26. Soon after 30 years of age there was a sharp rise among women, but the corresponding rise in men was delayed five years longer. After 59 in women there was a further presenile rise. A new clinical picture could now be seen, and what was once a typical paretic might be metamorphosed into a schizoid personality, while in others a hallucinatory psychosis might supervene. If a hallucinatory psychosis followed treatment, this fact was of grave significance.

A definite problem was presented by the patient who had been discharged in a good state of remission and then subsequently relapsed, and Dr. Nicol related several of these. It was matter for regret that some hospitals still precluded their general paralytics from receiving malaria therapy; no record had been published giving the fates of untreated general paralytics. The authors of this paper, however, had collected some evidence regarding untreated cases in the last ten years; 32 women and 23 men were not given treatment because of their poor physical condition on admission. Of the women, 10 were fulminating cases of the confused, manic, and depressed types; all died within seven months of the onset of the symptoms; 16 of the remaining 22 women were simple dementing types and 14 were dead within two years of the onset of the disease. No good recovery in women over 50 years of age had occurred, and only 3 men over 50 had shown a good remission. Every good remission case was ready for discharge from hospital 6 to 9 months after treatment; it could be confidently stated that if a patient was not well enough to be discharged within 9 months of the end of the treatment, hope of recovery could be abandoned. In both sexes there was a high recovery-rate in the pure confused, grandiose or manic types.

It was rational to regard the symptomatology of this disorder as due to the abnormal functioning of the brain cells affected by the infective process; this might be due to either irritation of the cells, or to their destruction, giving rise to either positive or negative phenomena. It was possible for the irritation to subside without causing any permanent damage, and then the concomitant symptoms would disappear, and a cure, or at least a remission, might occur. But when cell destruction had taken place this recovery could not occur. The grandiose delusions and the maniacal outbursts, could it was suggested, be regarded as due to irritation. In the mixed types it was rare to meet with a good recovery, and even in cases of the kind showing improvement there was always some permanent defect. The age-incidence of the disease was earlier in women than in men, but in the latter the fulminating types were more common, as also were the confused and the mixed grandiose and confused types. Sometimes the typical picture of G.P.I. was superimposed on a pre-existing psychosis, and since the use of malaria therapy the remission of G.P.I. had been demonstrated in some cases, only to lay bare the underlying mental disorder. Malaria was disappointing as a therapeutic agent for tabes, and also in its application to those associated psychoses with presumably latent syphilis. He asked whether malaria was a prophylactic weapon for preventing the subsequent development of G.P.I. In many cases following malaria therapy all serological findings became completely negative.

Dr. Nicol and his colleague held that malaria was definitely indicated in the treatment of the true case of G.P.I. Syphilis seemed to be declining in its incidence. It had become fashionable to treat many cases of general paralysis without certification and in general hospitals; during the last decade many hundreds had been so treated. Statistics as to results under these circumstances as well as those in mental hospitals were required; the recovery-rate would never reach higher proportions until the disease was diagnosed earlier by physicians and treated immediately.

The paper was discussed by the PRESIDENT, Dr. F. L. GOLLA, Dr. W. M. MCALISTER, Dr. G. M. BLAIR, Dr. RALPH NOBLE, Dr. ROSA STERN, and Dr. ROY M. STEWART.

ANNUAL DINNER

The annual dinner of the Royal Medico-Psychological Association was held on Wednesday, July 3rd, at Claridge's Hotel, London, with Dr. Reginald Worth, the president, in the chair. A large number of members and guests were present.

After the loyal toast the position of mental health in relation to medical practice was considered in an interesting speech by Prof. D. K. Henderson. He spoke hopefully of the prospects of psychiatry which, once a neglected Cinderella, had now become one of the chief problems before her elder sisters, medicine and surgery. Mental health must be regarded as part of the general problem of health. If psychiatry be neglected, the result will be appalling, for what, he asked, is the utility of many public health measures with a population below the proper mental standard? The study of psychiatry must, therefore, be more intense than it has been in the past—the population must be watched from the beginning, from birth onwards. The ideal man had been described as one with the English gentleman's mind in the body of a Greek God. Towards the physical side of this ideal much was being done and the same attention must be devoted to the mental side. We have, he said, a population of all sorts, a certain proportion of whom have a disordered mentality, and to meet the situation it is necessary that the medical profession should be better educated in psychiatric problems and that the goodwill of the public should be obtained by propaganda and the publication of satisfactory efforts. The General Medical Council, in a new scheme for a reformed curriculum recently issued, has now laid stress on the value of psychiatry, and everyone is now awake to the fact that the training of the medical profession generally should be directed in accordance with this view, which implied that the psychiatrist should find his place in a well-coördinated medical course.

Sir Arthur Robinson began by expressing the regret of the Minister of Health that he had been unable to be present to meet the Royal Medico-Psychological Association, as he had to fulfil an engagement made before the recent change of offices. The toast was the toast of "Mental Health," and he said that it was a matter of no small significance that the person who answered the toast was the Permanent Secretary of the Ministry of Health and also of Local Government. Prof. Henderson had stressed the necessity for regarding mental health as a part of the one whole problem of health. He noted that in the years since the Ministry of Health was established progress in regard to mental health had been noteworthy. For example, the relation between physical conditions and mental health had been more deeply explored, and the results of this research were fruitful. Again, in mental health as in physical health, there had been clearer recognition of the necessity for early treatment, and this was recognised by the power given by the Mental Treatment Act of 1930 to local authorities to establish out-patient clinics, and by 1934 no less than 134 of these had been established. Or again, the same Act had enabled public hospitals to receive patients without certification, and it was noteworthy that in 1934 no less than 20 per cent. of the direct admissions to public hospitals were admissions of voluntary patients. These were a few signs of progress and development. Obviously much more remained to be done. The development of relations between those responsible for mental health and between the members of the general medical profession was a matter of increasing importance, especially in regard to the extension of the relation of general hospitals to mental treatment. Again, there required to be still further education of public opinion as to the needs of mental health and what is required to make full provision for them. At this point he referred again to the linking up of mental health with general health in the areas of local government, and said that he thought that very careful consideration indeed was required before the Association committed itself to a policy in the local areas of divorcing the Mental Health

Committee from other committees of the local authority, such as the Public Health Committee. It appeared to him that in the long run better progress was likely to be secured in the conditions of local government which actually prevailed by accepting the fact that there must be the closest possible connexion between the various organs of government in the shape of the committees of a local authority.

Sir Arthur referred to the presence of Lord Macmillan, whose outstanding services on the Royal Commission on Lunacy and Mental Disorder were in the minds of all of them, and had resulted in the passing of the Mental Treatment Act of 1930, some of the results of which he had previously mentioned. He closed by bringing the best wishes of the Minister of Health to the service of mental health and to the Royal Medico-Psychological Association.

Sir *William Collins*, in submitting the toast of the Middlesex County Council, claimed as an old municipal hack, more acquaintance with the County of London, its Lieutenancy and its County Council than with Middlesex, though he had a nodding and neighbourly acquaintance with that county. He recalled the Local Government Act of 1888 when London was dealt with as an incident in rural administration, and the new County of London was largely carved out of the side of Middlesex. While the population of the County of London, he said, had been falling since 1901, that of Middlesex had grown from half a million to one and three quarter millions, a reminder that the County of Middlesex is becoming largely a dormitory for London, and the "green belt" of which many dreamt 40 years ago as the boundary of the County of London cannot now be realised, though possibly some such belt might be established around Greater London. When he was elected to the L.C.C. in 1892 and served on the asylums committee, two things, he said, impressed him particularly. One was the need of more thorough research into the pathology of insanity, and the other was the need for pensions for the asylums officers. With regard to the first he had endeavoured to promote research by inaugurating the laboratory at Claybury with the late Sir Frederick Mott as pathologist, while in 1909 he introduced into the House of Commons a Bill which became eventually the Asylums Officers Superannuation Act. In coupling with the toast the name of Mr. Alderman Button, the chairman of the Middlesex County Council, a body which had just promised £100,000 to the University of London, he recalled the fact that Mr. Button sat for a time in the House of Commons but was now pursuing the interests of both physical and mental health in the serener atmosphere of municipal life.

The toast was replied to by Mr. Alderman Howard Button, who referred to Middlesex as the county, save Rutland, with the smallest acreage, and an enormous population. The county was responsible for the conduct of two admirable mental hospitals, those at Shenley and Springfield, though the institutions were actually in Buckinghamshire.

The toast of the visitors was proposed by Dr. W. G. Masefield, who said that the assembly of guests was very representative, including visitors from Belgium, Denmark, France, Holland, and the United States of America, all of whom were in the charge of the members of the Association, on "a purely voluntary basis." The toast was replied to by Lord Macmillan and Lord Wakefield.

Dr. Robert Hutchison, president of the Royal Society of Medicine, proposed the toast of prosperity to the Royal Medico-Psychological Association, coupling it with the name of Dr. Worth, who briefly replied.

MATERNAL MORTALITY AND NUTRITION

A NEW INQUIRY

THE People's League of Health has established a committee to consider the nutrition of expectant and nursing mothers in relation to maternal mortality and morbidity.

At an inaugural luncheon held at Claridge's Hotel, London, on July 5th, Dr. C. O. HAWTHORNE, chairman of the council of the League, said that its reports were intended to inform and arouse public opinion and official action. The immediate object of the new committee was to study the question of food in relation to the health of the mother and to inquire what part was played by quantitative or qualitative errors of diet in the pathetic chapter on maternal mortality and morbidity. The solution of this grave problem would not be found in emotional appeals or in exaggerated statements, and still less in panic.

Lord HORDER, welcoming the enterprise, declared his belief that the core of the problem of maternal mortality and morbidity did not lie in any shortcomings of the doctor or midwife, and that the orientation of study should be shifted in the direction of the fitness of the mother to bear her child. Other attempts to solve the problem had failed, but this one had not been tested. The word nutrition must be read in the widest possible sense. Probably physical fitness, mental fitness, and biochemical fitness all contributed to the nutrition of the expectant and nursing mother.

Prof. JAMES YOUNG also commended the object of the League in this matter, but at the same time emphasised the importance of the obstetric aspect of the problem. Much maternal mortality had its origin in the ineffective standards of service brought to bear on the practical application of the subject. The investigations in Rochdale were extremely relevant; until recently this area had had the highest maternal mortality in the country but, as the result of a comparatively simple effort to improve the obstetric service, the mortality had come down in the most gratifying and dramatic manner. There was in addition a large group of conditions operating adversely, for example, the toxæmias and metabolic disturbances. There was strong evidence that some defect in the diet of the mother might be operating. The possibility could not be eliminated that in death from puerperal sepsis after normal labour there might be some factor determined by inadequacy of nutrition during pregnancy. Many conditions of pregnancy were directly related to diet, as, for example, the condition of the teeth. Nor must the child be forgotten; the condition of the mother had a great effect on the teeth and bones of the child and in this way the obstetric welfare of the third generation might be affected.

Dr. R. VEITCH CLARK suggested that the relationship between nutrition and pregnancy was probably biochemical; the word "nutrition" must be taken in its widest possible sense. He was not satisfied that there was any relation between maternal mortality and morbidity and the amount of food taken. Even the establishment of definite negatives would be a contribution of no little consequence.

Mr. Victor Bonney advocated the election of a small subcommittee for research: the services of people with both knowledge and time were essential for success.—Miss Olga Nethersole reported that the Royal College of Physicians of London at its next meeting would consider the appointment of a representative on the new committee.—Dame Louise McIlroy said that the investigation would entail two or three years' hard work, and the workers would probably find themselves up against some unknown quality in the patient herself.—Sir Comyns Berkeley observed that the subject was very complex.

A list of members of the committee follows. Asterisks denote that they are members in an advisory capacity only.

Sir Comyns Berkeley, F.R.C.P., consulting obstetric and gynæcological surgeon to the Middlesex Hospital, London.

Mr. Victor Bonney, F.R.C.S., gynæcological surgeon to the Middlesex Hospital.

Dr. J. J. Buchan, medical officer of health for Bradford.

*Dr. W. L. Burgess, medical officer of health for Dundee.

Prof. F. J. Browne, F.C.O.G., director of the obstetrical unit, University College Hospital, London.

*Prof. E. P. Cathcart, M.D., F.R.S., regius professor of physiology in the University of Glasgow.

Dr. R. Veitch Clark, medical officer of health for Manchester.

Miss M. L. Clark, L.L.A.

*Dr. G. P. Crowden, reader in industrial physiology at the London School of Hygiene and Tropical Medicine.

Prof. S. Lyle Cummins, M.D., David Davies professor of tuberculosis, Welsh National School of Medicine.

*Sir Henry Dale, F.R.C.P., F.R.S., director of the National Institute for Medical Research, Hampstead.

*Prof. L. S. P. Davidson, M.D., regius professor of medicine, University of Aberdeen.

*Prof. J. C. Drummond, D.Sc., professor of biochemistry at University College, London.

*Dr. J. S. Fairbairn, consulting obstetrical physician and gynæcologist to St. Thomas's Hospital, London; president of the College of Obstetricians and Gynæcologists.

Dr. Letitia Fairfield, a senior medical officer of the Public Health Department, London County Council.

Prof. Amy Fleming, F.C.O.G., director of the obstetrical and gynæcological unit, Royal Free Hospital, London.

Prof. W. M. Frazer, M.D., medical officer of health for Liverpool.

Dr. John Guy, medical officer of health for Edinburgh.

Sir Leonard Hill, M.B., F.R.S., late director of applied physiology, National Institute of Medical Research.

*Mr. Eardley Holland, F.R.C.P., obstetric and gynæcological surgeon to the London Hospital.

Prof. J. Johnstone Jervis, M.D., medical officer of health for Leeds.

Dr. R. C. Jewesbury, physician in charge of children's department, St. Thomas's Hospital, London.

*Colonel P. S. Lelean, F.R.C.S., professor of public health in the University of Edinburgh.

Dr. Helen Mackay, physician to the Queen's Hospital for Children.

*Sir Robert McCarrison, F.R.C.P., past director, Nutritional Research Pasteur Institute, Coonor, India.

Dr. A. S. M. Macgregor, medical officer of health for Glasgow (corresponding member).

Dame Louise McIlroy, F.C.O.G., late professor of obstetrics and gynæcology, University of London.

*Mrs. Ian Murray, Ph.D., of the University of Glasgow.

Dr. Elwin H. Nash, medical officer of health for Heston and Isleworth.

*Sir John Boyd Orr, M.D., F.R.S., director of the Rowett Research Institute, Aberdeen.

Dr. Thomas Orr, medical officer of health for Ealing.

Dr. W. H. F. Oxley, hon. medical officer, East End Maternity Hospital, London.

Dr. Eric Pritchard, pædiatrician to Queen Charlotte's Maternity Hospital, London.

Dr. H. J. Rae, principal medical officer of health for Aberdeen.

*Sir John Robertson, M.D., late medical officer of health for Birmingham.

Dr. G. W. Theobald, consulting obstetrician and gynæcologist, St. Mary Abbots Hospital, Kensington.

Sir Pendrill Varrier-Jones, F.R.C.P., director of Papworth Village Settlement, Cambridge.

Miss Jean Wishart, matron, Queen Mary's Maternity Home, Hampstead.

Prof. James Young, F.C.O.G., professor of obstetrics and gynæcology at the British Postgraduate Medical School, London.

MEDICINES AND SURGICAL APPLIANCES (ADVERTISEMENT) BILL

DEPUTATION TO THE MINISTER OF HEALTH

Sir Kingsley Wood, the Minister of Health, who was accompanied by Sir Edward Campbell, received a deputation on July 4th from the Parliamentary Committee on Food and Health.

The speakers were Lord Mamhead, Captain G. S. Elliston, Sir John Pybus, and Sir Francis Fremantle. The associations represented were:—

Advertising Association; Association of Municipal Corporations; British Medical Association; County Councils Association; Institute of Incorporated Practitioners in Advertising; Newspaper Society; Periodical Trade Press and Weekly Newspaper Proprietors' Association, Limited; National Association of Insurance Committees; Pharmaceutical Society of Great Britain; National Pharmaceutical Union; Surgical Instrument Manufacturers' Association Incorporated; Society of Medical Officers of Health; Parliamentary Medical Committee; and Parliamentary Committee on Food and Health.

Lord Mamhead, in introducing the deputation, recalled the fact that the Parliamentary Committee on Food and Health had first been constituted at a meeting held in 1911 and called by Dr. Addison, Lord Bledisloe, and others. It had always been a non-party and a lay body.

Captain Elliston said that the committee had had in preparation for some time the draft of a Bill to control the advertisement of medicines and surgical appliances. A Select Committee of the House of Commons, the appointment of which arose out of action taken by the Parliamentary Committee, investigated the question in 1912–14 and reported in favour of legislation. Several endeavours had been made since then to introduce legislation, but it had not been possible to make progress with a Bill. One of the difficulties had been that, in the past, it had been impossible to secure the agreement of the many interests concerned. The present Bill had been discussed with all the important interests affected, and a measure of agreement, never previously attained, had now been reached. The principal objects of the Bill were:

(1) To prohibit the advertisement of medicines, surgical appliances, or forms of treatment as effective for the cure or prevention of certain specified ailments, such as cancer and consumption, and

(2) To prohibit the publication of invitations to members of the public to obtain the diagnosis or treatment of these ailments by correspondence.

The Bill also contained clauses safeguarding the legitimate interests of those concerned, including newspapers and religious organisations.

Sir John Pybus, speaking as president of the Advertising Association, said that the Bill, if it were accepted in its entirety, would not affect adversely any legitimate trade interest. It would, indeed, be helpful to the existing work of the department of the Association charged with the voluntary regulation of advertisements. Although the Newspaper Proprietors' Association had not committed itself to support of the Bill, its representatives had taken part in the drafting of the Bill and, in view of the safeguards for the newspapers which the Bill contained, there was no need to anticipate any opposition from this Association.

The Minister of Health, in replying to the deputation, expressed appreciation of the valuable work done by the Committee, and congratulations upon the great measure of agreement secured for their Bill. Although much useful work was being done voluntarily, and many newspapers already set a very high standard in the matter, legislation was undoubtedly needed. The subject was one in which he had himself long taken interest and, at the time when he was previously connected with the Ministry of Health, legislation had been contemplated. It had not, however, then been possible to proceed with a Bill. The deputation would not expect him to give at the present stage any definite undertaking that the Government could introduce legislation. Nevertheless he would have the Bill examined and would make further inquiries as to the amount of support which might be anticipated for it. If these inquiries proved satisfactory he could assure the deputation that the introduction of legislation would be considered sympathetically, if the Government's general programme of legislation made this possible.

Sir Francis Fremantle expressed the thanks to the Minister on behalf of the deputation for their reception.

FACTORIES AND WORKSHOPS IN 1934

The Annual Report of the Chief Inspector of Factories and Workshops for 1934[1] has just been published. The year showed continued development of industry, notably in the south. More than half a million persons have been attracted towards London during the past seven years by new industries, representing an increase of some 27 per cent. of insured workers in the south-east. There was also evidence of a revival in some of the industries in the north, and in several places redundant cotton mills and weaving sheds are being converted to new purposes. Electric arc welding and the selenium cell are taking an increasing place in industry, and are playing a part in accident prevention. There has also been a revival in some of the rural industries, notably the production of Harris tweed. At the end of the year under review, the Department had on its registers 162,922 factories and 83,110 workshops, an increase of 2737 factories and a decrease of 3741 workshops on the preceding year. The Department received 3685 complaints, most of which related to conditions of employment; about half of them were substantiated upon inquiry. It also took part in a number of conferences.

One concerned a disaster in a bleaching works involving the death of four boys, and resulted in the formation of a committee to investigate the special risk. Two other conferences were undertaken in an attempt to design a code of rules to protect workers from the ill-effects of dust in the malting industry. Another considered steps to prevent danger to health from substances newly introduced into chemical manufacturing industries.

LIGHTING AND NOISE

Advance in lighting efficiency generally has not kept step with progress in such matters as fencing and ventilation. Most foundries are still poorly lit, though in some instances a very high standard has been reached.

Most of the workshops where clothing is made suffer from severe glare; employers and operators alike do not or will *not understand the necessity for reflectors of a suitable* type. Potteries and steel-tool cutlery and silversmiths' trades also suffer largely from bad illumination; the danger is not confined to eye-strain, but may result in accidents of various kinds. Some artificial silk and hosiery works have improved the lighting of their intricate processes very considerably, tilting the machines to obviate glare from the needles and providing local points easily adjustable to various heights of knitting frames. The Report mentions one recently equipped vitreous enamelling department where walls, floor, and ceiling are dead white, lighted with 350-watt bowl-spread lamps without reflectors. The result is complete absence of both shadow and glare. The excessive lighting contrasts often found in printing and book-binding works have been found to cause headache and eye-strain, which have in most cases been completely obviated by better general illumination. In some large steelworks and foundries, mercury-vapour lamps have been installed, and are claimed to be particularly suitable, because they are economical in consumption and give a high output of light with the elimination of glare and shadow.

The Report reviews a number of types of noise, both continuous and sporadic, which are encountered in different departments of industry. The most striking feature is the amazing tolerance of the workers. In weaving sheds, for example, the operators can talk quite easily where a casual visitor can hardly speak above the din.

Operators practically never complain of noise; complaints all come from residents in the neighbourhood. The Industrial Health Research Board has studied the effect of noise on efficiency and accidents and has detected a slight and persistent increase in output when ear protectors were provided. It seems reasonable to expect that a sudden noise might precipitate a mishap but there is no clear case on record. The only accident in which noise played a part was that of a man who went to oil a squeaking machine, contrary to rules, because he was irritated by it. The Department feels that the problem of the reduction of noise is, in the main, one for the designers of buildings. Individual firms have, however, tackled the problem with a good deal of success by lining departments with sound-absorbing felt or asbestos, walled between boarding, and by replacing old mechanisms by modern ones. Ear defenders were much appreciated by workers in a nail-making factory and by men testing aircraft engines; in other places their reception was mixed.

SAFETY IN INDUSTRY

The total number of accidents reported during 1934 showed an increase on those of 1933, no doubt largely reflecting the general increase in industry. The chief inspector fears that an increase in accidents must long remain the price to be paid for prosperity.

There were 785 deaths and 136,858 injuries. Transmission machinery accounted for 1,143 accidents, 38 of which were fatal; *and defective belt shifting accounted for a* number of serious accidents through machines suddenly starting when the workers did not expect it. Similar accidents were attributable to human carelessness. Fire, although not uncommon in industrial premises, did not cause much loss of life or injury, though one distressing outbreak caused the death of two boys in the celluloid store of an electric accumulator factory.

An improvement in trade conditions has been accompanied by a revival of interest in accident prevention. There is a tendency to abolish the safety committee and appoint a safety officer instead, but this practice is not regarded favourably by the Department. It is considered better to encourage the workers to take a keen personal interest in their own safety than to lead them to think that the employers regard safety as a matter for the management. Reports from various parts of the country are sometimes encouraging and sometimes unsatisfactory. One interesting innovation is that, in a certain works, carefully selected workmen have been appointed as "safety associates" for a period of three months. During that time their duty is to bring to the attention of the safety committee any dangers or risks which might otherwise escape notice. They will be replaced periodically by others. In another works a class of boys has been organised for instruction in safety principles and first-aid. The high accident-rate among young workers is specially mentioned by the Chief Inspector, who urges the importance of educating not only new entrants but also school-children. In a large gas works every accident is investigated by a jury of twelve workers. A chemical works in Wales succeeded in winning outright (having won it five times) a fine safety trophy competed for by a group of eight works, six in America and two in this country. Their record was 609,000 man-hours without a single lost-time accident from Dec. 13th, 1933, to Jan. 17th, 1935.

---

[1] H.M. Stationery Office, Kingsway, W.C.2, pp. 121, 2s. net.

Trade conferences have continued to meet to discuss safety in their particular trades. An investigation showed the value of these conferences by revealing that 12 per cent. of the accidents in a particular district would not have occurred if the precautions recommended by the trade conference of that industry had been carried out.

HEALTH IN INDUSTRY

Many attempts have been made to devise a system in which sickness-rates in industry can be recorded, and the health of industrial workers compared with that of the rest of the population. No satisfactory method has ever been discovered. In the opinion of Dr. J. C. Bridge, senior medical inspector, most ill-health in industry arises outside the factory. He thinks medical supervision is of the greatest value in assessing the gravity of minor sickness, since the boredom associated with repetitive work is likely to increase the significance attached to such sickness by the worker, and thus to increase the length of his absence from work. Medical supervision has also much value in counteracting the effect of irresponsible sickness certificates such as "gastritis due to employment." The effect on the health of the worker of the allegation that his illness is due to his work may be very grave. It would be much better if practitioners who suspect such a possibility would communicate with the Factory Department, in order that the diagnosis be made only after full investigation.

Experiments have been made in a few factories towards reducing the hours of heavy manual work, but there has been a regrettable tendency to employ workers under the age of 18 to the full limit of the legal hours. The reduction in cases of lead poisoning has not been maintained, chiefly because of the increase in the building of houses and an influx into the industry of untrained persons. Several steps have been taken to ensure the observance of the Pottery Regulations. There were only nine cases of aniline poisoning, the lowest since the disease became reportable. There were three fatal cases of benzene poisoning which is of interest in connexion with the study of aplastic anæmia. The extended use of chromium plating has been accompanied by an increase of chrome ulceration, and the industry does not seem to appreciate the value of frequent medical examination. Regular medical supervision seems to have a definite relationship also to the percentage of deaths from industrial skin cancer, which particularly affects cotton workers and gas workers. There have been no new cases of cancer of the nasal sinuses, to which attention was drawn in previous reports, but two further deaths have occurred among the cases previously reported. There is a suggestion that the condition may be associated with cancer of the lung, and the firm is doing its best to suppress all dust. The appearance of hand-made bricks and tiles has caught the fancy of the public, and there is a demand for them; they can be imitated cheaply by machinery which involves a process of sand-dusting. This exposes the worker to siliceous dust and will, in the opinion of Dr. Bridge, result in an increase of silicosis if precautions are not taken. The number of cases of dermatitis have very greatly increased, but this does not necessarily imply that the number of persons infected has increased in proportion. The causal agency is often obscure, and there is a tendency to ascribe any skin condition to the employment unless it is well recognised as a non-industrial type. A susceptibility test does not seem to be practicable, and the industries have to fall back on protection and care of the skin.

FIRST-AID AND FACTORY WELFARE

Most of the larger factories have good first-aid facilities but in the smaller factories the conditions are not good and in many cases the supply of dressings is inadequate. In one division no less than 30 prosecutions were taken against factory occupiers for failure to provide or maintain first-aid boxes. Carron oil is still supplied in first-aid boxes and is often used in preference to a burn dressing or other suitable preparation. The report suggests that local chemists might be circularised and informed of the type of dressing which will conform to the regulations.

There is some difficulty in getting workers to report slight cuts and scratches, and in one division three inquests were held on deaths from sepsis after minor injuries. Dr. Bridge, commenting on the attacks that have recently been made at inquests on the use of iodine for wounds, finds it difficult to understand why such a useful preparation should be held responsible for the fatal issue, as it was in one case of punctured wound, seeing that it is most difficult to render a punctured wound aseptic.

There is a rapidly extending improvement in the production of voluntary welfare amenities: comfortable chairs, small tables, pleasant colour schemes, and good messrooms. In a number of instances the appointment of women supervisors has entirely changed the atmosphere of the works. Internal discord, lack of discipline, and minor irregularities have been known to disappear completely on the appointment of a woman welfare worker or nurse. In other respects the personal factor is being considered more and more; for example in one factory a worker who has a relative undergoing an operation in hospital or seriously ill leaves his name and number at the office when clocking in. At intervals the office clerk telephones the hospital and keeps the worker informed of the patient's progress. In many places systematic efforts are made to trace symptoms of discontent to their origin and to remedy grievances. Several firms have realised the wastefulness of selecting entrants by putting a notice in the window, or applying to an employment exchange. One firm discovered that it had to engage 1000 people to select 200 suitable for their work, and are now thankful for the services of a trained psychologist. A large hosiery firm has experimented with prism lenses for employees engaged in linking fine-gauge hosiery.

The four women who tried the glasses for six weeks were so enthusiastic that every linker immediately asked for them, and now the supply of prism lenses has been extended to all the workers. The firm undertook to pay the oculists if National Health Insurance benefit was not available, and qualified opticians supplied the glasses at contract prices. Special consideration was given by the oculist and optician to the distance at which each linker worked, so that the glasses were suited to the individual. All the linkers who were examined by the oculist were found to have a refraction error, and in all but one case there was imbalance of the muscles. The amount of bad work is said to be greatly reduced.

The report closes with a short chapter on the Home Office Industrial Museum, which has attracted a considerable number of visitors, though as yet too few from among actual factory workers. Many examples have been furnished of the practical effects of a visit to the Museum, to which an extension is to be opened in the autumn.

OXFORD OPHTHALMOLOGICAL CONGRESS

THIS congress was held in the Department of Human Anatomy, Oxford, on July 4th, 5th, and 6th. At the opening session the retiring Master, Mr. Cyril Walker gracefully installed his successor Mr. Russ Wood, who then called upon Sir Harold Gillies to read his address on

PLASTIC SURGERY OF THE EYELIDS AND CONJUNCTIVAL SAC

Sir Harold pointed out that in plastic surgery a successful result was dependent on a correct diagnosis, particularly with regard to the amount of skin requiring replacement. This was often very much more than appeared at first sight, especially in cases of cicatricial ectropion. The best results were obtained with skin from one of the other eyelids, and failing this, from the back of the ear. If after operation the graft were found to be too pale it could be given a natural colour by tattooing. Another important general principle was to excise all scar tissue; this applied with particular force to cases of contracted sockets. Sir Harold showed many lantern slides of patients and a cinema film illustrating the general principles of plastic surgery. He also showed a series of 25 patients who had been the subject of plastic operations with remarkably fine results.

PAPERS AND DISCUSSIONS

In the afternoon, Mr. Tudor Thomas gave a description of *The Technique of Corneal Transplantation*. The operation was described in detail. Stress was laid on the importance of having a healthy donor cornea, of preparing the graft, and the hole in the recipient cornea. Mr. Tudor Thomas pointed out that the steps in the operation had been elaborated by experimental work on animals, and this work had been particularly valuable in ascertaining the best means of securing the graft in position. From the results obtained in 15 suitable cases, it appeared that material improvement could be expected from this operation in 75 per cent. of cases with opaque cornea, where the eye was otherwise healthy.

This paper was followed by a discussion on the *Results of Treatment in Retinal Detachment*. Mr. R. Affleck Greeves said he had treated 70 cases by Larssen's method of diathermy combined with trephining of the sclera and puncture of the choroid by a Nettleship's dilator. In 36 cases there was complete reposition of the retina with some improvement of visual acuity. Prognosis was found to depend mainly on the length of time the detachment had existed, the size and number of holes and the height of the intraocular pressure. The degree of myopia and the condition of the vitreous were not important factors. It was suggested that a hole never developed behind the equator of the eye, and that the so-called holes at the macula did not involve all the thickness of the retina. Aphakic cases gave poor results, only one out of five being successful.

On Friday morning, Colonel H. H. Smith spoke to his paper on *the Generation, Circulation, and Function of the Aqueous and their bearing on Cataract and Glaucoma* which had previously been circulated. He rejected the theory that the aqueous is a dialysate and suggested that it was secreted by the ciliary epithelium, drawing an analogy between these cells and those of the renal tubules. He also emphasised the importance of the pump mechanism of the scleral spur in bringing about drainage of the aqueous.

Mr. W. S. Inman then read a paper on *Emotional Factors in the Causation of Diseases of the Eye*. He gave many instances of eye diseases whose inception and course were influenced by some psychological upset though he had to invoke unconscious mechanisms to show the processes involved. Among his cases were some of acute glaucoma, ocular hæmorrhage, keratitis, irido-cyclitis, styes, and tarsal cysts. A lively discussion ensued.

In the afternoon, Dr. Ejler Holm, of Copenhagen, described a case of *Bilateral Cyclitis with Transverse Calcareous Band* occurring in a girl of 15 with typical Still's disease. The eye trouble had begun at the age of 5. The association of iridocyclitis with Still's disease is apparently rare, because the lecturer had been able to discover only one other case in the literature though there were several examples of iridocyclitis associated with polyarthritis in children.

Mr. Frederick Ridley read a paper on the *Permeability of the Cornea*. This is a subject which has not been investigated lately, largely because Leber in 1873 showed that it required a pressure of 200 mm. Hg to force water through a piece of excised cornea. Recent work shows however that the cornea acts as a semipermeable membrane, the permeability being greatest over the region of Schlemm's canal. This is because Descemet's membrane is relatively impermeable. If the cornea be in contact with blood-serum, its permeability is increased by 50 per cent.

Mr. Bernard Chavasse read an interesting paper on *Tests for Retinal Correspondence* and showed some ingenious instruments and slides he had devised for this purpose. Retinal correspondence, he said, is best investigated by the production of after images, which are different in the two eyes. He also suggested a valuable method of estimating stereoscopic vision, based on the principles laid down by Snellen for the measurement of visual acuity.

The afternoon session ended with a paper by Mr. Arnold Sorsby on *Skeletal Changes in some Congenital Eye Lesions*. These are commoner than is thought, and Mr. Sorsby urged his hearers to submit their patients with congenital eye lesions to a full general examination. He gave as examples of osseous deformities syndactyly, associated with aniridia; arachnodactyly associated with subluxation of the lenses, and polydactyly with retinitis pigmentosa. The present classification of cranial deformities was in a chaotic condition and Mr. Sorsby attempted to reduce this chaos to some degree of order by showing the difference between various cases of so-called "oxycephaly." He suggested that the use of this term should be restricted to cases with certain definite characteristics.

On Saturday morning Dr. BERNARD SAMUELS, of New York, read a paper on the *Recessus Hyaloideus Capsularis.* This is a space bounded posteriorly by the hyaloid membrane of the vitreous, anteriorly by the posterior capsule of the lens, and medially by Egger's line. Its size varies considerably and it can be examined by the slit lamp. In health it contains fibres arising from the vitreous. In glaucoma and diabetes the space has been found to contain pigment globules; in cases of injury, red blood-cells; in cases of uveal sarcoma, tumour cells.

Dr. GEORGE YOUNG described a modification of his operation of *Double Sclerectomy in Glaucoma.* After the trephined discs have been removed from the sclera, a special type of needle threaded with two pieces of silk is passed through one trephine hole and out of the other. One end of each piece of silk is cut short and the other is left just protruding from the conjunctival wound. At the end of eight days, each piece of silk is drawn out about 3 mm. and eight days later, they are removed entirely. The use of this seton obviates the need for massage of the globe after operation.

The last paper of the congress was read by Dr. D. V. GIRI on *Tebeprotin Therapy in Diseases of the Eye.* Tebeprotin, he said, was used with favourable results in disease of the eye as far back as 1922. It is a chemically pure protein derived from the human tubercle bacillus and the dosage can be exactly determined. It acts probably in a non-specific manner and is often of service in eye conditions which are not tuberculous. Dr. Giri gave an account of five cases in whom he had employed this remedy with satisfactory results. The injections were made subcutaneously below the clavicle, but he intends later to try subconjunctival injections, in view of the striking results obtained by Ilona Krasso.

DOYNE MEMORIAL LECTURE

This lecture was given by Mr. MALCOLM HEPBURN on June 5th. After a tribute to the founder of the congress, he went on to discuss the general principles governing the movement of pigment. He mentioned that apart from retinal moles and congenital pigmentation of the retina, pigmentary deposits were very rare in primary retinal diseases, whereas in disease of the choroid the pigment was always disturbed. This disturbance might be late in its occurrence, and in some cases might not be visible with the ophthalmoscope, even though subsequent histological examination proved its existence. Although differences in detail gave rise to a large variety of ophthalmoscopic pictures, the underlying pathology of many apparently diverse fundus conditions was the same. In spite of this, however, some kind of classification was essential and the lecturer suggested that the following five categories would include all choroidal disease: (1) inflammatory, (2) vascular, (3) colobomatous, (4) hyaline degenerative, (5) traumatic. The variations in the vision and visual fields in each type of case were discussed and their implications commented upon.

CONCLUSION

No account of the Oxford Ophthalmological Congress would be complete if allusion were made only to scientific communications. Nearly all the members are accommodated in Keble College, and live an undergraduate type of life for three days, having meals together in hall and meeting afterwards in the junior common room. A vast amount of shop is talked, and the information gathered is often of great value; moreover members have an opportunity of getting to know each other in a way that would be impossible were they all living in different hotels. There is a pleasant informality about the whole congress which makes it the finest busman's holiday that any ophthalmic surgeon could take.

The annual dinner was held on July 4th at Keble College. The Master alluded in his speech to the loss the congress had sustained through the death of Prof. Arthur Thomson, who had been its firm supporter since 1910. It was entirely owing to his kindness that the anatomical department of the university had been made available for the holding of these meetings.

The arrangements this year were, as usual, most efficient; the display by various firms in the commercial exhibition was much appreciated.

PUBLIC HEALTH

Special Schools or Special Classes?

THE conference of the National Special Schools Union, held recently in Edinburgh, provided an exceptionally attractive programme. One of its more interesting discussions centred round a controversy which, although old, has been recently revived—namely, what are the relative merits of special schools and special classes in the training of the mentally defective ? It soon became obvious that there was very little support of the latter alternative in the conference, its only defenders being two speakers from Leicester, where an interesting experiment is in progress in the education of retarded children in single classes. But as these children are not officially certified as defective, the classes are not technically "special" classes. It is true that Prof. Drever, the professor of psychology in Edinburgh University, who was described on the programme as presenting the case for special classes, did in the early part of his address speak of the present system of special schools as "wrong and quite indefensible," but it soon emerged that his real objections were not to special schools as such, but to the medical certification of mental defect which is still necessary for educational purposes and to the inclusion in special schools of children of low grade. The present school provides chiefly for children with intelligence quotient ranging from 50 to 70 approximately. His plea was for schools to educate children with quotient between 60 and 80. His proposals were therefore essentially those of the Wood Report of 1929, and he seemed to carry the sympathy of his audience very largely with him.

The question is largely one of population. Any area with a school population over 8000 should be able to maintain a special school. Below that level special classes in ordinary schools are the only possibility, but there are also areas where even a special class is an impossibility and where, therefore, the defective child has to be dealt with as a unit of an ordinary class. One county authority has a travelling inspector who periodically sees these children and gives advice on their individual tuition. Granted the necessary population, however, there is no question that the advantage educationally is with the special school which admits of a grading of the children and a consequent limitation of the range of capacity in any one class which is unattainable in a special class. The child has the further advantage, which was emphasised by Mr. Kennedy Fraser, the psychologist to the

Glasgow education authority, of a change of teacher from time to time, while the teacher, instead of being an isolated unit working with colleagues ignorant of and often unsympathetic with the difficulties of teaching "special" children, has the opportunity of sharing the experience of other teachers and discussing the problems raised by the individual children. If it be contended, on the other hand, that the special class gives the child the opportunity to mix with normal pupils and does not emphasise his segregation as the special school does, it can be replied in the words of Mr. Kennedy Fraser that defective children are "not too dull not to be acutely aware of their deficiencies when brought into contact with these normal children," deficiencies which make them often objects for the derision of their fellows and sometimes even of their teachers. In an ordinary school the subnormal child can be made to feel that he has possibilities of achievement.

If special schools encounter discredit in any area, it is most usually because children of too low a grade of defect are admitted who are, therefore, not strictly educable. The remedy for this, of course, is a raising of the standard of admission and the abolition of certification of defect so as to include larger sections of retarded children than is now legal. This would incidentally, by increasing the numbers of children who might be included, have the effect of justifying authorities in the establishment of "retarded schools" in areas where special schools are, under the present conditions, impossible. As Prof. Drever said, "the use of the term 'mentally defective' was an initial mistake" and too often has resulted in futile attempts to educate children really ineducable though perhaps trainable to a limited degree in respect of habits and simple tasks. Apart from official definitions of grades of deficiency, we have to *distinguish* those who are (1) ineducable and untrainable, (2) ineducable but trainable, (3) educable. The first two classes should not be under the care of education authorities. What is required is more concentration upon the educable and particularly the high-grade educable child who can undoubtedly, with suitable training—general and occupational—be socialised. The day special schools in particular have given ample proof of this possibility. The standard of admission naturally varies greatly in different areas, but there is probably on the whole better control of selection in the management of day special schools than of residential schools which tend too often to attract to themselves low-grade cases, and high-grades only when they present behaviour problems. It was admitted by one of the speakers at the Conference that about a third of the children now admitted fail to justify the hopes of their teachers. There must inevitably be children on the border line who should be admitted for varying periods on probation, but a raising of the standard of children selected would undoubtedly be of advantage in so far as it would permit the admission of high-grade children whom medical officers hesitate to certify but who obviously require some form of special education.

In striking contrast to Prof. Drever's utterance was that of a speaker at another session who, in support of the theory that juvenile delinquency is due mainly to mental defect, envisaged an extension of this term to include children up to an I.Q. of 90. His failure to give due weight to emotional factors in the causation of delinquency was criticised by other speakers and his use of the term defect received no support. Let the term defective be reserved for those obviously or proved by trial to be social misfits and its use as a necessary preliminary to education be abandoned.

Water-supplies National and Local

This year's presidential address to the Society of Chemical Industry was devoted to national water supplies—a subject that comes well within the purview of the Society since water is a chemical compound supplied in greater amount and in higher purity (seldom less than 99·95 per cent.) than any other. Mr. Edwin Thompson made it clear that there has been no national water policy in the past; indeed he maybe said to have shown that as yet we are only beginning to obtain data which may some day allow a national policy to be settled. The flow of the Thames has been gauged with some precision for about forty years, but the flow of most of our rivers is merely a matter of surmise, although the rainfall from which that flow is derived is well studied.

Mr. Thompson is not a believer in the possibility of the "water grid" and he quoted Mr. R. G. Hetherington as pointing out that an electric main costing a certain sum will supply over 36 times the population which a water main costing the same amount would supply, even assuming gravitational propulsion.

He raised another question —the softness of water—which was discussed rather more fully by Dr. Ernest Suckling and Mr. Philip Porteous in a paper read before the recent annual meeting of the British Waterworks Association. Suckling and Porteous set forth the reasons which led the Cambridge Water Company to soften their water from 18 down to 8 degrees of hardness and to do this by a base exchange process rather than by lime. It is interesting to know that the less cost of base exchange was a determining factor. In his part of the paper Dr. Suckling considered "the possibility of the desire and demand for soft water to become a craze or fashion not altogether to be commended"—a possibility which the president of the Society of Chemical Industry also had in mind. Whilst agreeing that there is an absolute necessity for a regular intake of calcium in the diet for normal development and the preservation of health he said there had been little medical support for the view that deficiency of calcium in water is responsible for dental defects and rickets. He holds that the advantages of water softening fully justify the cost.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JUNE 29TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 1; scarlet fever, 1563; diphtheria, 904; enteric fever, 62; acute pneumonia (primary or influenzal), 521; puerperal fever, 44; puerperal pyrexia, 121; cerebro-spinal fever, 14; acute poliomyelitis, 4; acute polio-encephalitis, 1; encephalitis lethargica, 7; relapsing fever, 1; dysentery, 5; and ophthalmia neonatorum, 122. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 2nd was 2753, which included: Scarlet fever, 811; diphtheria, 1000; measles, 43; whooping-cough, 377; puerperal fever, 24 mothers (plus 5 babies); encephalits lethargica, 270; poliomyelitis, 2. At St. Margaret's Hospital there were 21 babies (plus 11 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London there were no deaths from small-pox, 3 (0) from enteric, 19 (1) from measles, 4 (0) from scarlet fever, 17 (6) from whooping-cough, 17 (4) from diphtheria, 41 (8) from diarrhœa and enteritis under two years,

CORRESPONDENCE

THE FUTURE OF PHARMACY

To the Editor of THE LANCET

SIR,—In his presidential address to the British Pharmaceutical Conference, on which you commented last week, Dr. F. W. Crossley-Holland deplored the falling-off in the business of the pharmacist so far as the compounding of "drugs and galenicals" is concerned and urged his hearers to turn their attention to laboratory diagnosis. "It would," he said, "be of the greatest assistance to the doctor if he could depend upon the pharmacist to undertake the examination" of pathological specimens.

May I be permitted to question this statement? Its truth depends upon two assumptions: firstly, that the facilities for the examinations referred to are not at present fully available to medical practitioners and, secondly, that pharmacists are suitable persons to undertake them. As to the first assumption Dr. Crossley-Holland ignores the fact that there are already throughout the country a large number of laboratories established for the purpose of doing the work which he proposes should be taken over by pharmacists, the services of which are generally available to medical practitioners caring to make use of them. The majority of these laboratories are attached to voluntary hospitals and are in charge of medically qualified men and women who have made a special study of laboratory diagnosis. I believe that there is no district in England, Wales, or Scotland in which the services of such a laboratory are not available to the general practitioner.

Dr. Crossley-Holland's second assumption is that laboratory diagnosis may properly be undertaken by persons not possessing a medical training. He points out with truth that pharmacists have acquaintance with the methods of the laboratory bench; to make from this the transition to the assumption that in virtue of this familiarity the pharmacist is fitted to play the part of laboratory diagnostician is a very perfect non sequitur. It implies an implicit faith in laboratory methods as such, held by few who practise them. Most workers in diagnostic laboratories have at one time or another been embarrassed by being regarded as the priests of a peculiar ju-ju which in return for a suitable offering of a piece of meat or a bottle of urine will make oracular utterance. The scientifically minded laboratory diagnostician recognises that the results of his investigations play a part, sometimes lesser, sometimes greater, but a part only, in building up the picture of the morbid process which constitutes diagnosis and determines treatment. To play his proper part it is essential that the laboratory diagnostician have wide acquaintance with the whole field of medicine and that he move freely therein. To aid in diagnosis he must have knowledge of what he proposes to diagnose; failing this he is but a blind guide.

So well is the importance of laboratory diagnosis now recognised that the University of London has lately established a Diploma in Clinical Pathology, which may serve as the hall-mark of those having particular knowledge of, and skill in, the methods of laboratory diagnosis; this diploma is obtainable only by medically qualified men and women having special experience of this class of work.

Many pharmacists have in the past proceeded to the study of medicine and have come to adorn the profession of their second choice. The same course is still open to pharmacists wishing to qualify themselves for a closer contact with medicine.

I am, Sir, yours faithfully,

S. C. DYKE,
Hon. Secretary, Association of Clinical Pathologists.

Wolverhampton, July 8th.

MEDICAL HERBALISTS

To the Editor of THE LANCET

SIR,—Members of Parliament receive every month a journal called "The Medical Herbalist," which is described as the organ of the "National Association of Medical Herbalists of Great Britain." A legal M.P. in a recent public speech declared that he read the "Medical Herbalist" regularly, and it is indeed in many respects funnier than Punch.

The National Association of Medical Herbalists (N.A.M.H. for short) appears to control the "College of Botanic Medicine" at 46, Bloomsbury-street, London (which is also the registered office of the journal), through a council which appoints an "education committee," of which four "principals" (none medically qualified) are named in the Medical Herbalist of July, 1935, as giving instruction in "anatomy and physiology, materia medica and therapeutics, pathology and physical diagnosis, diseases of women and children, chemistry," and there is a further system of postal tuition in these subjects, forming part of the course leading to the issue of "Qualifications" to practice. Inspection of the calendar reveals that the College grant two "qualifications," both of which are called, sometimes "degrees," sometimes "diplomas," the users of these titles being apparently unaware that there is any difference between them. The "right" to practise "botanic medicine" is obtained by passing an oral examination founded on a curriculum which occupies three sessions of three months each, concurrently with a postal tuition course. The curriculum includes 32 separate subjects, and it is stated that there is a course of 12 lectures in each subject. Besides the subjects named above as being the responsibility of the "principals," bacteriology, general medicine, general surgery, gynæcology and obstetrics, pediatrics, orthopædics, urology, dermatology, otorhino-laryngology, ophthalmology, radiology and electricity, venereal diseases and infectious diseases are named as part of the course. Upon passing the examinations in this curriculum at the end of the third term, the "degree of L.C.B.M." is awarded, and immediately after this examination another oral test on the subject matter of the postal tuition course is held, upon passing which the "degree of M.N.A.M.H." is given. The two together are called the "conjoint degree," qualifying for practice. The fee for the whole course is 25 guineas, payable in advance, and a further fee of 5 guineas is payable on

---

(*Continued from opposite page*)

and 29 (4) from influenza. The figures in parentheses are those for London itself.

Birmingham reported 5 of the fatal cases of diphtheria, 4 of those from diarrhœa and enteritis, and 3 of those from measles. There were also 4 deaths from diarrhœa and enteritis in Manchester, and 3 in Hull.

The number of stillbirths notified during the week was 258 (corresponding to a rate of 38 per 1000 total births), including 44 in London.

registration, whereupon the happy herbalist is "entitled to use the letters L.C.B.M. and M.N.A.M.H." after his name. After the lapse of a year the holder of the "conjoint degree" may be awarded the "higher degree of D.B.M. (Doctor of Botanic Medicine)," on presentation of a thesis of not less than 5,000 words, and the payment of a fee of 25 guineas.

In the Medical Herbalist of February, 1935, the announcement was made that, relying upon a "Royal Charter" given to Herbalists in the reign of Henry VIII (34 and 35, Henry VIII, c. 8), which it was stated is still upon the Statute Book, the Council of the N.A.M.H. have resolved henceforth to give the degree of "M.D." replacing the previous "D.B.M." It is only fair to say that in the March number of the Medical Herbalist a protest was made by a correspondent who pointed out "the risk of prosecution" because of this "imitation" of medical degrees, but no notice apparently was taken of this protest.

There are only two authorities in London who have legal sanction to confer degrees in medicine, the Archbishop of Canterbury (this privilege is now obsolete) and the University of London. Upon the publication of the resolution cited above I consulted the Vice-Chancellor of London University and ascertained that, although the claim to which I drew his attention was obviously absurd, the University could not take action to prevent the imitation of its titles. If and when, however, any person actually uses the title of M.D. on the authority of the "degree" given by the "College of Botanic Medicine" it is probable that a prosecution could be undertaken—e.g., by the Medical Defence Union, for infringement of the Medical Acts.

The history of the statute thus exploited by the N.A.M.H. is interesting. It has never been repealed, but as the statute made no provision (and no provision exists) prescribing who shall exercise the privileges named in the statute it has remained essentially inoperative.

The first attempt to regulate medical practice in in England was made by the Act 3, Henry VIII, by which no person was allowed to practice as a physician or surgeon within the City of London or a radius of seven miles from it without examination or approval by the Bishop of London, outside that area by the Bishop of the diocese concerned. That statute has never been repealed, but is superseded by later legislation. The Act 34 and 35, Henry VIII, was apparently passed to allow certain persons "to minister medicines" without having the licence from the Bishops provided for by the earlier statute. Judicial interpretations of 34 and 35, Henry VIII, provide limitations severely restricting its scope. Thus it has been laid down that its effect is that it "does not extend either in words or intent or meaning to give liberty to any person to practise or exercise for gain or profit." The parties licensed by that statute are "such persons as shall be good honest people, as old women and such as are inclined to give their neighbours physic through charity and piety," and the diseases in which "potions" are thus admissible were limited to three: "stone, strangury and ague."

These limitations are of course not indicated in the claim put forward by the Council of the N.A.M.H. that the Act 34 and 35, Henry VIII, legalises the indiscriminate practice of herbal medicine in this country. How dangerous that practice has become may be gauged by the Coroner's inquests in which herbalists have been concerned.

I am, Sir, yours faithfully,

House of Commons, July 8th. E. GRAHAM LITTLE.

AGGLUTINATION OF VIRUS BODIES

To the Editor of THE LANCET

SIR,—Prof. J. G. Ledingham's letter in your last issue makes it clear that he himself in his paper in 1931 recognised the priority of Paschen in the matter of the agglutination of the elementary bodies of vaccinia by specific serum. Had he pursued his researches more meticulously and written to our common friend Prof. Paschen for further details he would have found that Paschen's first observation was actually made in 1911, two years before the published paper to which Prof. Ledingham refers. The expression therefore "not very profound or critical" that Prof. Ledingham is kind enough to apply to my references applies even more appropriately in this instance to his own.

The real point at issue between Prof. Ledingham and myself is the question as to the relative merits of the macroscopic and microscopic methods of detecting the specific flocculation of a virus. Now, Sir, the first observation of the specific flocculation of vaccinia virus was made neither by Paschen nor by Ledingham, but by Tanaka in Japan as long ago as 1902, and curiously enough Paschen himself in his paper in the *Deutsch. med. Woch.* of 1913 referred to by Prof. Ledingham seems to have missed this paper, which was published in the *Centralblatt f. Bakteriol.*, Abt. 1, 1902, Orig., xxxii., 726. The following notice of this observation is taken from my special report "Studies of the Viruses of Vaccinia and Variola" (M.R.C. Special Reports No. 98, 1925, p. 15).

> "The first observation that a suspension of vaccine lymph undergoes flocculation when brought in contact with immune serum was published in 1902 by Tanaka, who in the course of an epidemic of small-pox in Japan found that fluid from a serous effusion in a small-pox patient when left in contact with a suspension of vaccine lymph for several days at 37° C. produced a coagulation phenomenon akin to the Pfeiffer-Gruber-Widal reaction. Control observations with normal serum, and hydrocele and ascites fluids when mixed with vaccine lymph in the same way, proved negative. This observation was confirmed in 1904 by Freyer (*Centralbl. f. Bakteriol.*, Abt. 1, 1904, Orig., xxxvi., 272), who found that the serum of a well-immunised calf or rabbit as well as that of a vaccinated man produced flocculation of a suspension of calf lymph."

It was this observation of Freyer that Paschen refers to as preceding his own in the paper published in 1913. The occurrence of the flocculation reaction in question, however, was contradicted by v. Pirquet in a paper published in the *Wien. klin. Woch.*, 1906, xix., 1407, and his prestige and authority were so great that further progress in the practical application of the reaction for recognising cases of small-pox was delayed until publication in 1925 of the M.R.C. Report referred to above and the later work of Burgess, Tulloch, and Craigie. As stated before, the flocculation was shown by Craigie to depend upon two factors; an agglutination of the E.Bs, and a precipitation of their soluble products.

With regard to the microscopical procedure employed, first by Paschen and eighteen to twenty years later by Ledingham, in which the elementary bodies were shown to be agglutinated, while the method has undoubtedly the merit that the purified virus agent can be observed, as Ledingham and Eagles were the first definitely to prove, the procedure is by no means free of criticism. First of all, as Paschen pointed out, it is liable to be complicated by the simultaneous presence of a precipitin reaction; secondly, it involves the use of that museum-piece the hanging drop chamber; and thirdly it means a long and tedious wait of 48 hours or even longer during which the hanging drop may dry up, or in warm weather such as we have recently been experiencing moulds, &c., may get in. The whole tendency in the application of specific serological methods of diagnosis in practical medicine to-day consists in the employment of macroscopic methods, which save both time and labour, and have the further conspicuous merit that the absorption test can be used as well to check results. Moreover, the microscopic agglutination of elementary bodies is at present badly in need of further control observations.

I am, Sir, yours faithfully,

M. H. GORDON.

St. Bartholomew's Hospital, E.C., July 7th.

STERILITY AND PSYCHONEUROSES FOLLOWING LUMBAR SYMPATHECTOMY

To the Editor of THE LANCET

SIR,—My attention has been drawn by Dr. Levy Simpson to the erroneous conclusions which might be drawn from my paper on this subject which you published on April 6th. Investigations into the after-results of some hundreds of operations performed at the Mayo Clinic and by Prof. J. R. Learmonth and Prof. E. D. Telford have shown that lumbar sympathectomy or ganglionectomy, unilateral or bilateral, is never followed by any sexual difficulty. On the other hand, Prof. Learmonth tells me that in his experience presacral and inferior mesenteric neurectomy in the male is invariably followed by loss of ejaculatory power and consequent sterility, though not by impotence; the fibres concerned in this loss traverse the presacral nerve. Presumably the latter operation was performed in the two cases referred to in my paper.

I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, July 5th.

CLEFT PALATE

To the Editor of THE LANCET

SIR,—I think I can best answer Mr. Wardill's letter by quoting two passages from his own pen. In his letter in your last issue he writes: "The whole object of the procedures advocated by myself has been that of restoration of function, and this can only be attained by operation based on sound anatomical and physiological principles. The proof of success lies not in the appearance of the suture line or in the apparent mobility of the palate, but in the ability of the patient to open and close the nasopharyngeal valve." Yet his paper in the *British Journal of Surgery* (October, 1933) contains the following sentences: "Among my greatest disillusionments in cleft-palate surgery was the case of a young woman . . . upon whom the operation of pharyngoplasty with repair of the palate was performed. The operation resulted in a perfect palatopharyngeal mechanism which complied with all the tests, and for many weeks I spent much time in correcting her bad habits, until in the end she was sound perfect. At this time she was engaged to be married, and, marriage ultimately taking place, I did not see her till some months after, when happening to meet her in the street, I was amazed to find that she had become one of the worst cleft-palate speakers I had ever heard."

It has been stated many times that a patient regarded as a surgical success is a functional failure, and even Mr. Wardill admits this. The converse is also true. Surely, then, some form of speech training is essential. There are many recorded cases of a functionally perfect result following such training "in spite of" surgery.

Having read much of the extensive literature that has grown up around the surgery of cleft palate, and having tried several means of closure of the cleft, I now use Veau's technique which I have modified slightly. Veau's operations are described in detail in his book, which however is written in French. I have published an (admittedly inadequate) account of Veau's technique taken from this source in THE LANCET (1933, i., 515). I am, Sir, yours faithfully,

DAVID LEVI.

Harley-street, W., July 6th.

GOLD TREATMENT OF TUBERCULOSIS

To the Editor of THE LANCET

SIR,—Your last issue contains the results of a statistical inquiry into the results of gold therapy in pulmonary tuberculosis by Dr. B. A. Peters and Dr. C. Short of Bristol. So sweeping is the generalisation inherent in their conclusions, and so great its clinical significance if it is correct, that it warrants a close examination of the evidence upon which it is founded.

In the first paragraph of their paper Drs. Peters and Short say, in regard to the assessment of the therapeutic value of any particular agent in pulmonary tuberculosis, "If any method of selection is used an imponderable error is introduced." Later they state that "during the past three years those not treated with gold have been slight cases or cases with pleural effusion . . . or moribund cases." Thus, by their own admission they must have employed *some* selection, thereby introducing an "imponderable error"! That this selection was capable of introducing a very significant "error of sampling" is shown by a scrutiny of Table III.: in the 1930–34 experience, only 171 out of a total of 492 (35 per cent.), and in the 1932–34 experience, 147 out of 299 cases (49 per cent.), were treated by gold: further, a simple subtraction sum shows that in the years 1930–31 only 24 of 193 cases (13 per cent.) received gold.

With the statement "during the past three years those not treated with gold have been slight cases or cases with pleural effusion in whom the prognosis was very favourable without special treatment, or moribund cases," let us couple "the tuberculosis officer who is responsible for allocating cases to our institution informs us that the cases sent to us have been chosen on the same basis during the whole ten years—another institution receiving the majority of the earlier cases." It follows that the above-mentioned "slight cases or cases with pleural effusion" form a relatively insignificant fraction of the cases untreated by gold—i.e., 65 per cent. in the first and 51 per cent. in the second observation period. This conclusion surely stultifies the major premise of the theorem that "an improvement in the results of a five years' working should be evident if gold were of any value," because the gross preponderance of "moribund" cases in the total experience can only falsify the statistical issue.

When one seeks to determine exactly *what* type of case was treated with gold, the only answer appears to be that they were neither very early cases nor moribund ones: between these two extremes lies a host of possible permutations and combinations of clinico-pathological variables, and the criteria upon which the authors decided to exhibit gold in any given case remain shrouded in obscurity. In particular, no mention is made of radiological examination which so often compels the assessment as an advanced case of what clinically is a mild or moderately severe one. So again, by a lack of clarity in description of their material, the authors expose themselves to a possible statistical error.

The assessment of the value of a therapeutic method, whether statistically or otherwise, necessarily connotes that the method has been employed in accordance with the canons of its correct usage as laid down by past and current clinical and experimental research. Contemporary opinion in regard to gold therapy for pulmonary tuberculosis has it that at least 5 g. in all should be administered, and, for certain experimentally established facts, by the intravenous route. Drs. Peters and Short say their cases ". . . have had gold in the form of Crysalbine, Allochrysine, or Myocrysine in the usual weekly doses of 0·1–0·5 g. for six to eight weeks, followed in many by a repeat course after an interval of six weeks." Thus it seems that the efficiency of gold therapy in their hands can be indicted upon the grounds that the preparations used by them were administered by the *intramuscular* route, and more, that the total dosage was an inadequate one; for we are not told exactly how many cases had a "repeat" course.

To summarise:—The sweeping generalisation, sorrowfully made by Drs. Peter and Short, that gold in the therapy of pulmonary tuberculosis is quite valueless, has for its foundations very important errors of sampling, a lack of definition of selective criteria, and a misuse of the therapeutic agent. Their conclusion contrasts strangely with that of a carefully controlled statistical study such as Stub-Christensen's (Tubercle, 1931, xiii., 49).

I am, Sir, yours faithfully,

Queen Anne-street, W., July 8th. CEDRIC SHAW.

DUODENAL EXTRACT IN DIABETES MELLITUS

To the Editor of THE LANCET

SIR,—Your annotation of July 6th under this title omits reference to a paper by my old chief, Prof. J. Hill Abram, in THE LANCET (1906, i., 220) on "The Acid Extract of the Duodenal Mucous Membrane as a remedy in Diabetes Mellitus." He dealt fully with the problem in this and two subsequent papers published in 1906 in the *Biochemical Journal* in collaboration with Prof. Benjamin Moore (who first suggested the use of duodenal mucosa) and E. S. Edie. Their reasoning was:—

> "If, for the purpose of argument, we take it that the duodenum does yield a chemical excitant for the internal secretion of the pancreas, and that in the absence of the internal secretion glycosuria results, then there are three places in the chain at which weakness due to functional or other disarrangement may occur and lead to a breakdown and the appearance of diabetic conditions. First, the breakdown may occur at the duodenum, on account of the non-secretion of the excitant; secondly, the breakdown may take place at the pancreas, so that although the excitant is formed at the duodenum and carried to the pancreas, yet these cells are not capable of excitation, either from complete morbid change or from some functional alteration in their metabolism; and thirdly, there is the possibility that even when the duodenum is normal and supplying its excitant, and although the pancreas is also normal and yielding, as a result of the action of the excitant, its internal secretion, yet there are changes in the oxidising tissues such as the liver or muscles which prevent the oxidising function of these from coming into operation.
>
> "It is clear that it is only in the first class of case that benefit might be expected to follow in a diabetic from administration of extracts of duodenum, even granting that the experimental difficulties of administration had been so overcome that the active material entered the circulation and reached the pancreas as if it had naturally been formed in the patient's duodenum.
>
> "Accordingly, it is scarcely to be expected that in all cases administration of extracts of duodenal mucous membrane will cure, or even benefit, diabetics, and to prove the existence of a specific chemical excitant for the internal secretion of the pancreas formed in the duodenum, it is only necessary to show in a fair percentage of cases that abolition of glycosuria follows administration of the extract of duodenal mucous membrane."

It is interesting to compare the first paragraph of the above with the following summarising paragraph in the paper which, thirty years later, is dealt with in your annotation:—

"The results suggest that three types of diabetes exist—e.g., (1) from lack of activation of the pancreatic islands by a duodenal factor, (2) from loss of Islands of Langerhans, and (3) an insensitiveness of the organism to insulin." (Duncan, Shumway, Williams, Fetter: Amer. Jour. Med. Science, March, 1935, p. 418).

I am, Sir, yours faithfully,

Liverpool, July 9th. HENRY COHEN.

SODIUM AND THE SUPRARENALS

To the Editor of THE LANCET

SIR,—The annotation on this subject in your last issue refers to a conclusion of Loeb and his colleagues that if adrenal insufficiency in man is not relieved by the administration of salt it will not be relieved by commercial cortical extracts in ordinary doses. This is contrary to my clinical experience and its acceptance would, I believe, cause unnecessary suffering. For the latter reason I write this brief note, although it is not my intention at the moment to discuss the therapeutic value and limitations of salt or sodium therapy.

I am, Sir, yours faithfully,

Harley-street, W., July 7th. S. LEVY SIMPSON.

IRISH MEDICAL ASSOCIATION.—The annual meeting of this association was held in Dublin on July 3rd. Dr. Robert J. Rowlette was re-elected president, and Dr. John P. Shanley was elected vice-president. The business of the meeting was divided into two sessions—one for scientific discussions and one for the ordinary business of the association. The scientific session was held in the forenoon, and there were two discussions—the first on immunisation against diphtheria, and the second on puerperal sepsis. The discussion on immunisation was opened by Dr. J. P. Shanley, and communications were also made by Dr. C. J. McSweeney, medical superintendent of Cork Street Fever Hospital, Dublin, and by Dr. J. C. Saunders, medical officer of health for the city of Cork. The discussion on puerperal sepsis was opened by Dr. Bethel Solomons, and communications by Dr. Gibbon FitzGibbon, Dr. N. McI. Falkiner, and Dr. John McGrath were read. Both discussions were highly practical and were greatly appreciated by the members present. In the evening the members of the association and their guests dined together at the Dolphin Hotel. Among the principal guests were the Lord Mayor of Dublin, the Attorney-General of the Irish Free State, the president of the Royal College of Physicians of Ireland, the president of the Royal College of Surgeons in Ireland, and the governor of the Apothecaries' Hall.

Arrangements made for amalgamation with the British Medical Association's Irish branches are described on p. 90.

OBITUARY

THOMAS McCRAE, M.D., D.Sc. Toronto, F.R.C.P. Lond.

PROFESSOR OF MEDICINE, JEFFERSON MEDICAL COLLEGE, PHILADELPHIA

AFTER an illness lasting more than a year death released Thomas McCrae from increasing disability in spite of which he had courageously carried on his teaching. Coming of an old Galloway fighting stock he was born on Dec. 16th, 1870, at Guelph, Ontario, as the eldest son of Lieut.-Col. David McCrae and his wife Janet Eckford. His brother John was the pathologist, physician, and poet who wrote "In Flanders Fields" and died on active service in January, 1918, a few days after he had been appointed consultant physician to the Imperial Forces overseas. The two brothers were educated medically at Toronto University and went as post-graduates to work under Osler at the Johns Hopkins Hospital. After this their careers diverged; John returned to Canada and at McGill University taught first pathology with J. G. Adami and later clinical medicine. Thomas remained at the Johns Hopkins Hospital and as resident, instructor in medicine and in charge of the clinical laboratory, resident physician, and associate professor of medicine became a most successful clinical teacher. Like W. S. Thayer he was very closely associated with Osler, his chief, often travelling with him and helping and collaborating in medical publications; for example in "Cancer of the Stomach: A Clinical Study" (1900), in "Modern Medicine" (1907) which was a system of medicine (at first in seven, later in six volumes) running into a second and third edition (1913, 1925), and in the later editions of Osler's well-known text-book.

Often in this country in the summer with his chief, before the latter came to Oxford as Regius professor of medicine, and later with Mrs. McCrae, he became M.R.C.P. in 1901 and was elected F.R.C.P. in 1907. As a bachelor he lived for some years in the same house in Baltimore as W. H. Welch; in 1908 he married Amy Gwyn, a niece of Sir William Osler, and in 1912 he left Baltimore to become professor of medicine at the Jefferson Medical College, Philadelphia, in succession to Prof. J. C. Wilson who survives him. During the European war he was for a time Lieut.-Colonel C.A.M.C. and head of the medical service of a Canadian War General Hospital. Well known on both sides of the Atlantic for his writings and with many personal friends he took an active part in American medicine, being secretary (1917–26) and president (1930) of the Association of American Physicians which corresponds to the later established Association of Physicians of Great Britain and Ireland, of which he was, with Lewellys Barker, elected a foreign honorary member last year. At the Royal College of Physicians of London he gave the Lumleian lectures in 1924, taking as his subject the clinical features of foreign bodies in the bronchi (THE LANCET, 1924, i., 735, 787, 838), on which his experience with his colleague Chevalier Jackson made him an exceptional authority. In 1927 he received the honorary degree of D.Sc. from Toronto, his own University

With a fine presence McCrae radiated good nature and inspired immediate confidence. The sympathy of his numerous friends will go out to his childless widow.

HENRY JOHNSTONE CAMPBELL, M.D., F.R.C.P. Lond.

THE death occurred on July 4th, in Dartmouth Cottage Hospital, of Dr. H. J. Campbell, late consulting physician to the Bradford Royal Infirmary and professor of forensic medicine at the University of Leeds.

Henry Campbell, the third son of Peter Campbell of Brackley, was born in London in 1859 and educated at University College School, proceeding to Guy's Hospital for his medical education. He qualified with the English double diploma in 1887 and graduated as M.B. London in 1889 with first-class honours in forensic medicine. At Guy's Hospital he made a mark in the school, being senior demonstrator of physiology and lecturer on elementary biology in the school, while he was also a Hunterian professor of physiology at the Royal College of Surgeons of England. He was elected assistant physician to the East London Hospital for Children in 1891, and held the post for four years, during the last two of which he was also assistant physician to the City of London Hospital for Diseases of the Chest. In 1895 he went to Bradford on his election as physician to the Bradford Royal Infirmary and now became a prominent figure in the educational life of the Victoria University as lecturer in forensic medicine and toxicology at the Yorkshire College. He was elected F.R.C.P. Lond. in 1898, and on the institution of the University of Leeds was appointed professor of therapeutics and pharmacology in the university, while his other posts included those of consulting physician to the Victoria Hospital, Keighley, to the Bingley Hospital, and to the Bradford Eye and Ear Hospital. Dr. Campbell made important contributions to medical literature. Early in his career he wrote useful records in the Guy's Hospital Reports and a work on elementary biology. He edited the English translation of Hertwigs "Cell," and published clinical papers in the *Quarterly Journal of Medicine*, the *British Medical Journal*, and the *Edinburgh Medical Journal* over a large range of subjects.

During the war Dr. Campbell was physician to the Bradford War Hospital and at the conclusion of hostilities retired to Dartmouth. Here he took a great interest in municipal affairs, was elected to the Devon County Council, made J.P. for the county, and was mayor of Dartmouth for six years. He served on many important committees of the county council, was chairman of the Governors of Dartmouth Grammar School, and a member, generally as president, of many local bodies concerned in the maintenance of health and the promotion of sport.

FLORENCE STACEY-CLEMINSON, M.B., B.S. Lond., J.P.

THE death occurred on June 30th of Dr. Stacey-Cleminson, well known as a medical practitioner and public worker in Hull.

Florence Stacey, a New Zealander, studied medicine at the London School of Medicine for Women, and graduated as M.B., B.S. London in 1909. She held appointments at the Royal Free Hospital and in 1911 was appointed house surgeon to the Victoria Hospital for Children, Hull, and from that time forward spent her professional life in Hull. She soon gained a place on the honorary staff of the hospital, and practised in partnership with another doctor, Dr. Mary Charlotte Murdoch, at that time also on the staff of the Victoria Hospital. On the death of Miss Murdoch, Dr. Stacey married Mr. Cleminson and shortly afterwards discontinued private practice, though her services were often in request as a consultant. She now devoted herself to public work of which she had considerable experience as a prominent person in the organisation of the National Council for Women. She was appointed a justice of the peace and served on the panel of justices to the juvenile court where her special training made her services of particular value. She was a member of the health and public service committee of the Hull corporation and touched the social side of the city at many points, making her mark on the life of Hull.

GEORGE CHARLES PEACHEY, L.R.C.P., L.R.C.S. Edin.

THE death occurred on Sunday last, July 7th, of Dr. George Peachey who made a considerable mark as a medical journalist and historian. Peachey, who was descended from a long line of doctors, was born in Calcutta in 1862, the son of Thomas Peachey, I.C.S. He received his general education at Taunton school and proceeded thence to St. George's Hospital and the University of Edinburgh, where he qualified with the Scottish double diploma in 1887. At first in general practice in Berkshire, he held various appointments, among others that of medical officer and public vaccinator to the Wantage Union, but his inclinations led him to return to London and take up literary work in connexion with medicine. He contributed to various magazines biographical sketches of famous men of science, was the author of a short life of Sir William Savory, and he undertook the writing of the history of St. George's Hospital with the support of Clinton Dent, then senior surgeon to the hospital. After Dent's death the work was not completed in accordance with the original design. He was a British delegate to various historical congresses in Rome and Budapest, and was for a long time associated with the conduct of the *Medical Press and Circular* where much of his historical or antiquarian writing appeared. He was a member of the Society of Genealogists, for pedigree rather than heredity interested him; and he was British delegate on more than one occasion at historical congresses. The direction of his work led him to become familiar with the developments of medical organisation over a long if modern period, and he described the origin of voluntary hospitals as we now understand them in the *Hospital*. In 1928 Peachey delivered the Thomas Vicary Lecture at the Royal College of Surgeons of England. The lecture entitled "The Homes of the Hunters" was published in THE LANCET (THE LANCET, Feb. 18th, 1928, p. 360), and was as much concerned with William Hunter as with his better known brother, John. With its full illustrations and sound reflections on the careers of the famous brothers the essay revealed Peachey as a man of real literary talent.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Overcrowding in Scotland

IN the House of Commons on July 3rd Mr. SKELTON, Under-Secretary of State for Scotland, moved the third reading of the Housing (Scotland) Bill. He said that overcrowding in Scotland was a serious danger and difficulty. The powers and the finance which this Bill gave to the local authorities armed them satisfactorily to deal with the problem as it had never been dealt with before. The Bill would achieve a double result: low wage earners, or those with limited financial means, would be given an opportunity of being rehoused at rents which they could afford to pay; and that those whose means would enable them to take houses at an economic rent would not be subsidised by their fellow citizens. The provisions even with regard to those areas would ensure that the central sites of the bigger cities were used and not allowed to degenerate. One cause of misunderstanding in regard to the Bill was removed by the undertaking given by the Secretary of State for Scotland on the second reading and the alteration made in Committee to deal with the fears of those who thought that the object of one of the clauses was to force the owners of existing property to adopt forthwith a new standard. Another misunderstanding was that the Bill would result in the indiscriminate slaughter of existing housing accommodation. Where a survey showed that existing houses were suitable for replacement for occupational purposes this fact would be borne in mind in relation to the housing programme. There was a superfluity in Scotland of one- and two-roomed houses, the former unsuitable for a family, though the two-roomed house might well be suitable to a newly married couple, and even a couple with one child. But many two-roomed houses in Scotland dated back to the middle years of the nineteenth century, built in vast rookeries with lighting, air space and passage space entirely out of date. Some of these would undoubtedly go. There were, however, two-roomed houses built shortly before the war with proper modern amenities, and he did not believe that these ran any risk.

Mr. N. MACLEAN said that they needed a completely new set of circumstances, and the sooner they got them the better for the health of the people of Scotland. It was not merely an overcrowding question but a health question, and he wanted to see the features embodied in this Bill extended in a more generous manner, the machinery simplified, and the methods to be adopted by the local authorities handled in a different way. The Government departments should see to it that the local authorities attended to their duties under the housing legislation; some had been remiss in the past. The Labour Party hoped that there would be, in this Bill or in a later measure, additional powers given to the department to sweep out of existence the great curses of single apartment and room and kitchen houses that had been so much to the detriment of the health of the people of Scotland.

Sir ARCHIBALD SINCLAIR supported the Bill on behalf of the Liberal Party.

Sir IAN MACPHERSON said that the problem of overcrowding did not exist in the same way in the rural districts as it did in the towns. The problem in the rural areas was not so much overcrowding as the habitability of the houses. What they wanted in the Highlands was a small subsidy to recondition houses. In some of the burghs of the North of Scotland they could find individual houses as bad as any of the slums in the great cities.

After further debate,

The Bill was read the third time and passed.

Prison Administration in Scotland: Medical Officers' Duties

The House of Commons on July 4th went into Committee of Supply on the Civil Estimates.

On a vote for salaries and expenses of the Prisons Department in Scotland,

Sir G. COLLINS, Secretary of State for Scotland, said that his attention had been drawn to the inspection of bedding in prisons. All the regulations were to be completely reviewed in the light of modern thought and modern outlook. The Department were securing a site near Carstairs for a modern criminal lunatic building and when that building was erected there would be a big transfer of criminal lunatics from Perth Prison to Carstairs.

Mr. N. MACLEAN said in the Report of the Prisons Department they found that certain prisoners were certified under the Mental Deficiency and Lunacy (Scotland) Act, 1913, during 1934. The number included quite a number of youths as well as men. There was one case in which he was interested of a lad of 17 years of age who was sentenced in April, 1934, to 60 days' imprisonment and was transferred to Stoneyetts Certified Institution on May 17th in terms of an order by the Secretary of State under Section 10 of the Act to which he had referred. This lad might perhaps lack intelligence, but he was by no means mentally defective. He was treated in one of the special schools in Glasgow. To the best of his (Mr. Maclean's) knowledge the lad was still at Stoneyetts Certified Institution. He had tried to get this lad released but had failed to do so. He had several cases which bore some resemblance to this case, and he entertained grave feelings about what was likely to happen if the Secretary of State obtained the further powers for which he was asking in the Criminal Lunatic Bill.

Mr. LEONARD said that prisoners on their reception into prison had to wait in a detention cell for a medical examination and that the period between their reception and the medical examination was sometimes an hour or two hours, and that the conditions under which the prisoner was in that cell were anything but comfortable. He also wished to raise the question of the medical inspection of prisoners. He had received from the Secretary of State in reply to a question a list of the duties of medical officers and Rule 225 (8) stated:

> "A medical officer shall see every prisoner at least once a week, so as to ascertain his general state of health, physical and mental, and whether he is clean in his person and free from disease, and if his clothing and bedding are sufficient, and shall record the results of his inspection in the journal."

That rule was quite explicit, easily understood and commendable, but he was informed that these things could not be done by any medical officer if the practice that held good in Barlinnie Prison was adopted in prisons elsewhere. He was informed that this weekly inspection was somewhat in the nature of a single-file parade past the medical officer and if that was the case it was totally inadequate and no medical officer irrespective of his ability was capable of attending to the details in the rule by such a cursory survey of the people under his charge.

After further debate,

Sir G. COLLINS, Secretary of State for Scotland, said that the points Mr. Leonard had raised would be examined. The practical administration of Barlinnie and other prisons would be scrutinised. In regard to the case referred to by Mr. Maclean it was undoubtedly true, and he (Sir G. Collins) regretted it, that intimation of the removal of this young lad was not sent to the relatives by the prison governor, and steps had been taken to see that such a thing would never occur again. During the last few months he had made thorough inquiries to see whether the lad could be released, but his present information was that it would not be in his interests to release him. He would, however, consult an outside doctor untrammelled by departmental influence in the matter.

Mr. MACLEAN said this case had been mismanaged from the commencement by the authorities. Might he ask that the medical man or men whom the right hon. gentleman intended to ask to examine this case should do so away from the environment of Stoneyetts Certified Institution; that they should be asked to certify the lad free from the surroundings of a lunatic asylum?

Sir G. COLLINS: I will have inquiries made, but I must not be taken as agreeing that the inquiry shall be outside a particular place.

Mr. MACLEAN: Will it not be prejudiced if the examination is made in the mental institution?

Sir G. COLLINS: Everything will be done above board to inquire whether this youth should be retained where he is.

After further discussion the debate on the vote was adjourned.

In the House of Commons on Monday, July 8th, the University of Durham Bill, which has already passed through the House of Lords, was read a second time. The money resolution in connexion with the Bill was agreed to in Committee.

The money resolution in connexion with the Criminal Lunatics (Scotland) Bill was also agreed to in Committee.

National Health Insurance Bill

In the House of Commons on July 8th the National Health Insurance and Contributory Pensions Bill was considered in Committee.

Mr. TINKER moved to omit the provision in paragraph (4) of Clause I. that a person should not be entitled to maternity benefit during an extended insurance period unless and until, having again become employed within the meaning of the Bill, he had been so employed for at least 26 contributory weeks in a period of not more than four consecutive contributory half years and had paid 26 contributions. The cash benefit in maternity cases was especially important, because it was required at the time when there was most need in the house.

Sir KINGSLEY WOOD (Minister of Health) said that in addition to the provisions of maternity benefit under the National Health Insurance Act local authorities provided facilities in their hospitals and homes in connexion with schemes of maternity and child welfare. Most women who took advantage of those facilities made payment for them. It was difficult to extend the cash payment in respect of maternity without so extending sickness and disablement benefit for men as well as women. Unless the financial scheme of the Bill were wholly recast it would not be possible for such payments to be made. He had no doubt that a number of the approved societies would not be able to make the payments.

After further debate,

Sir KINGSLEY WOOD said that he would, however, look into the matter again.

The amendment was withdrawn.

Mr. RHYS DAVIES moved the following new Clause: "Every assignment of or charge on, and every agreement to assign or charge, any remuneration payable to a medical practitioner in respect of the administration of medical benefit shall be void, and, on the the bankruptcy of any medical practitioner entitled to such remuneration, the remuneration shall not pass to any trustee or other person acting on behalf of his creditors." The purpose of the new Clause was to expose some anomalies which had crept into panel practices in some parts of the country. The position, briefly, was this: A medical student, when qualified, might be poor when starting his career. To buy a practice he must have money. He believed that in some cases the young doctor got so involved in the hands of money-lenders that the fact led to his practice suffering. He believed that within the medical profession arrangements existed whereby young doctors were helped in starting their careers, but he was not referring to that angle of the case. The position was stated in a definite and official form in the Report of the Annual Conference of the Association of Insurance Committees. He was not criticising the young doctor who borrowed money, but he wanted to lay it down definitely that money should not be lent under such conditions for its repayment as would harass the doctor to the detriment of his private or panel practice. It was not suggested that such cases were common.

Mr. SHAKESPEARE (Parliamentary Secretary to the Ministry of Health) said that there was no evidence, except in an infinitesimal number of cases, that the efficiency of the panel practitioner was being affected by the fact that he used the security of his practice to advance himself in his career. It would be putting too great a disability on a young panel practitioner to prevent him from doing this. The real safeguard was that it was a matter for the British Medical Association to see that the panel practitioner was not made the prey of unscrupulous people. More and more reputable insurance societies were making provision to enable practitioners to borrow on reasonable terms. The Ministry would watch the position in consultation with the British Medical Association to see that the panel practitioner was not disadvantaged by mortgaging his security.

The new Clause was withdrawn.

The Bill passed through Committee and was reported to the House.

HOUSE OF COMMONS

MONDAY, JULY 8th

Destruction of Locusts and Malarial Mosquitoes

Mr. McEntee asked the Secretary of State for the Colonies whether any experiments by spraying from the air for the destruction of locusts or malarial mosquitoes had been carried out in any area controlled by his department; and, if so, were the experiments considered to be successful.—Mr. Malcolm MacDonald replied: Certain experiments against locusts were carried out last year by the Government of Northern Rhodesia. These showed that it is possible to destroy locusts in flights by spraying them with finely divided poison dust from aircraft. The report on these investigations was considered by the Third International Locust Conference, in September last, which recommended that further work should be carried out with a view to developing these methods of locust control. I am not aware of any experiments in the destruction of malarial mosquitoes by similar methods in any of the Dependencies.

WEDNESDAY, JULY 3RD

Maternal Mortality in Ceylon

Mr. Thomas Williams asked the Secretary of State for the Colonies what was the maternal mortality-rate in Ceylon for the latest year for which figures were available; and how many deaths were involved.—Mr. Malcolm MacDonald replied: The maternal mortality rate in Ceylon for 1933 was 18·6 per 1000. The number of maternal deaths involved was 3832.

Mr. Williams: Is the right hon. gentleman aware that this constitutes the highest maternal mortality figure of any civilised country in the world, and can he say what steps the Government are taking to deal with the matter?

Mr. MacDonald: The figures represent a considerable decrease on what they have been, and in recent years there has been a steady improvement. The Government are taking various steps to meet the situation.

Mr. Williams: Is the right hon. gentleman not aware that the 18 per 1000 births compares very badly with the 4 per 1000 births in this country, and that there is very real room for improvement?

Mr. MacDonald: The fact that there has been a steady improvement in recent years shows that we are aware of the problem and that we are doing everything we can to solve it.

Unemployment Regulations and Meals for School-children

Mr. Cleary asked the Minister of Labour whether he was aware that in the city of Liverpool the Unemployment Assistance Board was making deductions in respect of meals given to necessitous school-children; and, if he could say under what regulation of the Board this was done, and whether he would have this practice stopped, in view of the fact that the Board of Education, by making grants towards the cost, was encouraging the granting of such meals, particularly in industrial areas, in order to enable children to benefit from the education afforded in the schools.—Lt.-Col. Muirhead, Parliamentary Secretary to the Ministry of Labour, replied: I am informed that the Board's practice in the treatment of school meals is as set out in the Appendix to the Memorandum on the Unemployment Assistance Regulations 1934, presented to Parliament in January last (Cmd. 4791). As indicated there, the Board entirely ignores all meals given upon a doctor's certificate that a child is suffering from a specific pathological condition and also all those consisting of milk and other special forms of provision. Moreover, other meals are only taken into account where they exceed twelve a week, and the adjustment made in the allowance is based on a moderate estimate of the saving to the household, approximately one penny per meal. The Board inform me that they are keeping a close watch on the working of these arrangements.

Mr. Cleary: Will the meals in question granted to the necessitous school-children come under the exemptions mentioned by the hon. gentleman in his reply?

Lt.-Col. Muirhead: I cannot answer that question without notice.

Mr. Cleary: Is it within the knowledge of the hon. gentleman that deductions of the character mentioned are being made in Liverpool?

Lieut.-Col. Muirhead: I understand that that is so. It is being done in accordance with the instructions issued last January.

Mr. Cleary: In view of the fact, that the Board of Education make a grant of 50 per cent. towards the cost of these meals, and by recent circular are endeavouring to encourage very definitely their provision in industrial areas, is the hon. gentleman aware that the action of the Unemployment Assistance Board is militating against the policy of the Board of Education?

Lieut.-Col. Muirhead: I can only say that the Board are acting under the powers granted to them by this House.

Mr. G. Griffiths: If the public assistance committee give these meals without taking them into account what authority have these other people to take them into account, because there is a standstill order?

No answer was given.

Local Authorities without Superannuation Schemes

Mr. Tom Smith asked the Minister of Health, the number of the local authorities that had not put superannuation schemes into operation.—Sir Kingsley Wood replied: The authorities who have not adopted the Act of 1922, or who have no schemes under local Acts are (apart from Parish Councils and a number of miscellaneous authorities) County Councils, 12; County Borough Councils, 16; Borough Councils, 132; Metropolitan Borough Councils, 2; Urban District Councils, 349; and Rural District Councils, 251.

State Grants for Medical Research

Captain Fuller asked the Minister of Health, what bodies or persons were receiving grants for medical research from public funds; and whether any notable results had been obtained in the last 10 years.—Mr. Duff Cooper, Financial Secretary to the Treasury replied: As regards the first part of the questions, I would refer my hon. friend to an answer which I gave on July 9th last. The provision for a grant to the Medical Research Council in the current year is £165,000. As regards the second part of the question, I fear it is impossible within the limits of a Parliamentary reply to do justice to the advance of medical science in the last ten years and to the part which state-aided bodies and persons have taken in that advance. I can only refer him on the subject generally to the Annual Reports of the Medical Research Council.

Pregnant Woman and Prison Sentence

Mr. McGovern asked the Secretary of State for Scotland, whether he was prepared to release Mrs. Kelly who was an expectant mother and due to give birth to a child in 5 weeks' time and was sentenced to six months' imprisonment for alleged perjury in the Garngad Rioting Case.—Sir Godfrey Collins replied: A medical report which I have obtained and examined shows that Mrs. Kelly's confinement is not expected until about the end of September and that she is well, in good general health and doing light work in the prison, and as stated in my reply to the hon. Member yesterday she will be removed to a hospital outside the prison for her confinement. The doctor will keep her under particular care and she will receive special medical attention. In no case can I find that pregnancy by itself has been regarded as a reason for release from prison. Having given further consideration to this case I regret that I can find no special circumstances which would justify me in recommending the release of Mrs. Kelly from prison at the present time.

Meals for Necessitous Unemployed Juveniles

Mr. TINKER asked the Minister of Labour, if he had considered the resolution passed by the Association of Education Committees calling upon the Government to introduce legislation to enable local education authorities, if they so desired to provide mid-day meals for necessitous unemployed juveniles attending approved full-time courses of instruction, and empowering the Ministry of Labour to bear the whole or part of the cost of providing such meals; and what reply he intended to give.—Mr. E. BROWN replied: I am not satisfied that a case has been made out for introducing the legislation necessary to enable local education authorities to provide meals at junior instruction centres, but I can assure the hon. member that the position is being, and will continue to be carefully watched.

Mr. TINKER: Will the right hon. gentleman make inquiries in the various localities and ask the authorities to send him cases in which it is felt that it is necessary that something should be done?

Mr. BROWN: That has been done. If the hon. member will consider the report of the National Advisory Council for Juvenile Employment in England and Wales, which is composed of representatives of the Association of Education Authorities, the National Confederation of Employer's Organisations, the Trade Union Congress General Council, the teachers organisations and the juvenile advisory committees, he will find that that report dated Jan. 20th, 1934, unanimously recommended against this course.

Mr. TINKER said that as he was not satisfied with the reply he would call attention to this matter at the earliest opportunity.

TUESDAY, JULY 9TH

Puerperal Fever Serum in L.C.C. Hospitals

Mr. GROVES asked the Minister of Health whether serum for puerperal fever was used, or had been used, in the hospitals under the administration of the London County Council.—Sir KINGSLEY WOOD replied: I understand that serum for puerperal fever has been used in one of the hospitals referred to, but that its use has now been discontinued.

MEDICAL NEWS

Royal College of Surgeons of England

Election to the Council.—On July 4th three fellows were elected into the council to fill the vacancies caused by the retirement of Sir Cuthbert Wallace, Mr. Leonard Gamgee, and Mr. L. R. Braithwaite. The result of the poll was as follows:—

	Votes.	Plumpers.
Leonard Ralph Braithwaite (Leeds) ..	838	33
Sir Cuthbert Sidney Wallace (St. Thomas's)..	829	40
Seymour Gilbert Barling (Birmingham) ..	709	15
Ernest Cranmer Hughes (Guy's)	648	68

In all 1187 fellows voted, including 208 fellows resident out of Great Britain and Northern Ireland; in addition eight votes were found to be invalid. Sir Cuthbert Wallace, Mr. Braithwaite, and Mr. Barling are all elected for the full period of eight years.

University of London

At recent examinations the following candidates were successful:—

D.M.R.E.

F. M. Abeles, P. A. Flood, Daniel Hugo, E. G. Lynch, Mahendra Mani, Stanley Nowell, and T. C. Wasson.

At University College the Schafer prize in physiology has been awarded to Dr. D. H. K. Lee and the Bayliss-Starling scholarship in physiology to Mr. R. A. Gregory.

University of Manchester

At recent examinations the following were successful:—

M.D.

By Thesis.—B. R. Bramwell, J. A. K. Brown, Eli Davis, E. M. Greaves, M. C. G. Israels,* Florence V. Stephen-Lewis, C. F. White,* and D. J. Williams.†

* With commendation. † Gold medal.

By Examination.—K. H. Jackson.

CH.M.

Branch I.—H. T. Simmonds.

FINAL EXAMINATION FOR M.B. AND CH.B.

John Charnley, Eleanor B. Clarke, Mary A. C. Cowell, T. F. Davey, Samuel Franks, E. H. Heilpern, K. H. Higson, R. E. Hirson, L. L. Husdan, J. I. A. Jamieson, T. S. B. Kelly, W. E. Kershaw, A. F. Mackay, R. L. Parish, J. N. Parker, G. R. Rhodes, Leslie Margaret Ross, Cyril Royle, H. L. Settle, Dennis Shute, Clifford Tetlow, Roland Thornley, H. J. Wade (with distinction in medicine), and Margaret I. Williams.

Part I.—Forensic Medicine and Hygiene and Preventive Medicine.—S. G. Abelson, Beryl A. Barlow, Muriel J. Brayshay, J. C. Brundret, P. J. Burke, J. H. B. Cantley, Caroline J. Chalmers, Violet Cohen, D. L. Cooke, G. D. Dawson, Benjamin Flacks, Jacob Goldman, David Halpern, Alan Hargreaves, B. P. R. Hartley, J. A. Herd, Isaac Hesford, James Hilton, C. B. Holland, V. T. Lees, John Meynell, Evaleen N. A. Milligan, Eleanor M. Mills, E. J. Mitchell, W. S. Parker, Benjamin Portnoy, D. A. Richmond, A. L. Robertshaw, E. N. Rowlands, Aboudi Shashoua, R. M. Shaw, Nina Shtetinin, H. B. Slater, A. M. L. Smith, F. W. Smith, Nathan Taylor, D. J. Walker, and E. P. Whitaker.

University of Sheffield

At recent examinations the following candidates were successful:—

M.D.

D. L. Brown and Hyman Finklestone-Sayliss.

FINAL EXAMINATION FOR M.B., CH.B.

Part II.—Charles Axinn (with second-class honours); and J. C. Jolly and Ronald Scott.

University of Birmingham

At a congregation on July 6th the following degrees were conferred:—

M.D.—P. C. P. Cloake.

M.D. (State Medicine).—Alfred Elliott.

Ch.M.—F. A. d'Abreu.

M.B., Ch.B.—J. L. Collis (first-class honours); J. C. Bishop, J. T. Corbett, G. L. Gale, Leopold Goldman, R. G. Record, R. A. Shove, and A. G. M. Wilson (second-class honours); F. L. Bland, M. I. Cookson, A. L. Deacon, E. G. Dommen, V. J. Downie, C. C. Houghton, H. B. Hunt, W. H. G. Jones, T. B. Kenderdine, G. B. Miller, J. S. Price, W. S. Rees, A. E. Roberts, Harry Taff, and B. W. Walford.

University of Liverpool

At recent examinations the following candidates were successful:—

M.D.

J. L. Clegg, Elinor M. Gelling, R. G. Gornall, Mary F. Lacey, J. E. S. Lloyd, G. A. C. Lynch, J. Polonsky, Kathleen E. Slaney, and E. S. Smith.

FINAL EXAMINATION FOR M.B., CH.B.

Second Class Honours.—A. C. Brewer, B. J. Green, and W. Parke.

Part B. (1924 *Regulations*).—F. Harrison, J. R. Jones, and E. G. Watson.

Part III. (1929 *Regulations*).—Agnes Y. Bowie, J. L. Brown, G. V. Craine, H. R. G. Davies, V. K. Drennan, S. G. Griffin, R. L. Hartley, Clarice Hughes, J. E. E. Hughes, Mary M. Hurst, G. E. Jones, E. W. Knowles, H. S. Lanceley, Ethna W. Little, Sheelah Little, G. B. Marsden, A. G. H. Menzies, J. G. Rogers, and A. R. Sibbald.

Part I.—A. M. Abrahams, O. G. Bark, S. Bender, W. E. G. Bradford, K. W. Cameron, L. H. Chandler, E. Claitman, R. I. Cohen, K. W. Evans, J. G. Fox, J. Gendle, T. C. Gray, A. S. Hall, Elsie O. Hughes, H. Hughes, R. R. Hughes, T. S. Jones, J. Kay, J. Lawson, A. T. Leggate, M. Libman, H. K. Lucas, C. McGibbon, G. B. Manning, R. Marcus, E. H. Moore, W. J. Patton, W. H. G. Patton, R. S. Riley, W. A. M. Robinson, J. P. G. Rogerson, P. J. Rooney, A. C. Smerdon, A. R. Unsworth, J. Wajnerowicz, N. Waldman, S. R. Warren, T. E. Whitby, Evelyn M. Williams, G. E. O. Williams, Margaret E. Williams, R. B. Wright, and H. Zalin.

Part II.—L. V. Arundel, S. Ball, O. G. Bark, D. Barton, A. B. Bateman, A. H. Baxter, J. C. Birchall, J. G. Bozle, P. S. Byrne, H. Cantor, Eileen Chrimes, Eunice M. Clapham, S. E. Cooke, F. W. Crook, J. B. David, R. E. A. Davies, F. C. Deller, T. M. Doran, Mabel M. Drummond, Beryl Edgecombe, E. W. Evans, Jennet Evans, A. Fairbairn, A. J. Gill, N. M. Hancox, R. P. Harbord, H. F. Harwood, L. Henry, G. E. Hesketh, A. B. Higginson, E. A. K. Hoppins, F. Lanceley, J. Leiper, H. R. W. Lunt, K. S. E. MacRae, F. T. Madge, J. V. Manning, G. D. Owen, Kathleen M. Pearson, M. N. Phillips, G. Platt,

A. Simpkin, A. Singer, W. S. Sutton, A. C. T. Vaughan, R. E. D. Wheeler, and T. E. Whitby.

D.P.H.

Part I.—Nancy L. Lewis, J. B. Mackie, and Patricia I. Unsworth.

Part II.—A. R. Arulpragasam, A. T. Jones, E. Somasekhar, and J. V. Walker.

D.M.R.E.

Part A.—D. Menzies.

Part B.—D. Menzies, F. O. Pilkington, R. G. Reid, E. Siung, and R. F. Wynroe.

D.T.H.

G. P. A. Amirtha Nayagam and H. R. Shone.

Royal Institution

The managers of the Royal Institution have elected Dr. Edward Mellanby, F.R.S., Secretary of the Medical Research Council, to be Fullerian professor of physiology in succession to Sir Grafton Elliot-Smith. It is expected that Prof. Mellanby will give his first course of lectures in the autumn.

British Postgraduate Medical School

The second refresher course for general practitioners will be held during the fortnight commencing July 15th, 1935. The plan of the course will be on the general lines of the first one, described in our columns last week. The outside specialists taking part in this course are as follows: Dr. C. W. Buckley (Chronic Arthritis); Dr. Geoffrey Evans (Essential Hypertension: Its Diagnosis and Treatment); Dr. A. F. Hurst (Disorders of the Colon); Dr. E. Mapother (Psychiatry in General Practice); Dr. J. L. Livingstone (Asthma); and Prof. L. J. Witts (Common Types of Anæmia: Their Diagnosis and Treatment). Similar courses will be held during the fortnights commencing Sept. 16th and Nov. 18th. Other students can be admitted at any time for a course of hospital practice for periods of six months. Further particulars can be obtained from the dean of the school, Ducane-road, Shepherds Bush, London, W.12.

Rockfeller Medical Fellowships

The Medical Research Council announce that on behalf of the Rockefeller Foundation of New York they have made the following awards of travelling fellowships for the academic year 1935–36:—

David Fyfe Anderson, M.D. Glasg., professor of midwifery and gynæcology, Anderson College of Medicine, Glasgow, and assistant obstetric surgeon, Royal Maternity and Women's Hospital, Glasgow.

Norman Rupert Barrett, M.Chir. Camb., demonstrator of anatomy and chief assistant to the surgical unit, St. Thomas's Hospital.

Alexander Colin Patton Campbell, M.B. Edin., clinical tutor in medicine, Royal Infirmary, Edinburgh; and assistant lecturer, department of pathology in the University of Edinburgh.

Douglas Harry Kedgwin Lee, M.B. Sydney, Sharpey scholar, department of physiology, University College, London.

John Eugene Anthony O'Connell, F.R.C.S. Eng., demonstrator in anatomy, St. Bartholomew's Hospital Medical School.

Robert Walmsley, M.B. Edin., assistant in anatomy, University of Edinburgh.

All the fellowships awarded this year are tenable in the United States. Dr. Lee has been appointed on modified conditions while receiving emoluments from another source.

West London Medico-Chirurgical Society

The fifty-third annual dinner of the society was held at the Trocadero Restaurant, London, on Wednesday, July 3rd, the president, Mr. Howard M. Stratford, in the chair. After the loyal toasts the president presented Mr. Hugh Cairns with the West London Triennial Gold Medal for his recent work in neurosurgery, who in thanking the president said that in thus honouring him they were honouring his colleagues in neurosurgery. The award showed that neurosurgery had taken a secure place in medicine, but the progress that had been made had not been achieved without great effort on the part of the surgeons, and such recognition was of the highest possible encouragement.

The toast of the president and the West London Medical Society was proposed by the Lord Chief Justice, who said that if it had not been for the members of the medical profession some present might not have been born, and some would not have survived. In speaking to the good work done by the society, he recalled that it was founded in 1882 by a surgeon named Keetley, for many years on the staff of the West London Hospital, of whom it had been said that although he was very deaf nothing ever escaped him. The objects of the society were to advance medical science, to help coöperation between the general practitioner and the hospital with its specialised services, to hold scientific meetings for the presentation of research work, to discuss clinical cases, and to recognise and honour those who distinguished themselves in medical science. Associated with the society was the Cavendish lecture which was the only oration delivered under the ægis of the society. In proposing the toast Lord Hewart coupled with it the name of the president, a distinguished Kensington practitioner whose war service was remarkable, for he received his commission on the first day of the war, served on four fronts up to 1918, was torpedoed and twice invalided before he came home "pavilioned in splendour and girded with praise." Mr. Stratford in reply, thanked the Lord Chief Justice for his kind references and said that the members of the society were proud of their body, which was composed of general practitioners and specialists; indeed, he thought that if they had not got the general practitioners they would not have got the consultants. Sir William Osler had said that attendance at medical societies kept a man's mind open, and the president thought that if medical men in London were to use the advantages of the various medical societies there would not be the same need for them to have special postgraduate study. The year of his office had been most successful, but while the enrolment of new members had been one of the largest they had had, he could have wished that there had been more general practitioners among them.

Dr. V. B. Green-Armytage proposed the toast of the guests and kindred societies, and Prof. A. M. Low replied. Mr. L. E. C. Norbury also acknowledged the hospitality of the West London Medical Society.

British Empire Cancer Campaign

Sir Holburt Waring, president of the Royal College of Surgeons, vice-chairman, presided at the fifty-fifth quarterly meeting of the grand council of the Campaign, held at 12, Grosvenor-crescent, London, on Monday last. The following grants were approved: £655 to Dr. Alan Greenwood, of Edinburgh, for the breeding of disease-free brown leghorn fowls; £500 to Mr. F. C. Pybus, of Newcastle, through the North of England Council of the Campaign, for salaries of assistants and laboratory expenses for one year, and £150 for the purchase of apparatus for Dr. Lumsden, working at the London Hospital. The finance committee and grand council also authorised the renewal of the appointment of two assistants to Dr. Lumsden at £500 and £450 per annum.

Lord Horder, the chairman of the scientific advisory committee, submitted a scheme for the coördination of clinical cancer research which had been occupying the attention of the committees of the Campaign for some time. Lord Horder informed grand council that the scheme, which envisages an organisation for coördinating on a scientific basis clinical cancer research, had now received the unanimous support of all the teaching hospitals in London, the medical committee of the L.C.C. as well as a number of specialised hospitals in the metropolitan area. Grand council gave authority for carrying into effect the proposals made, and a general committee is to be formed for this purpose consisting of the nominees of all the coördinating institutions, together with the following representatives of the Campaign: Lord Horder, Dr. R. G. Canti, Sir Charles Gordon-Watson, Mr. J. P. Lockhart-Mummery, Mr. Cecil Rowntree, Mr. Eric L. Pearce Gould, and Mr. W. H. Ogilvie. It was agreed that the scheme should be carried out in the London area in the first instance, but it was hoped that it would be extended to all parts of the country and to the Empire in due course as a result of the experience gained.

Mr. Cecil Rowntree, F.R.C.S., one of the two British representatives and a vice-president of the "Union Internationale contre le cancer" reported to grand council that a general assembly was held on May 4th in Paris, attended by 43 delegates representing 34 countries, and that the international committee had made preliminary arrangements for the convening of an international conference on cancer in Brussels in September, 1936.

It was announced that the annual general meeting of the Campaign will be held on Nov. 25th.

Appointments

DAVIDSON, MAURICE, M.D. Oxon., F.R.C.P. Lond., has been appointed Hon. Consulting Physician to the Papworth Village Settlement, Cambridge.

Vacancies

For further information refer to the advertisement columns

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.

Association of Surgeons of Great Britain and Ireland, 65, Portland-place, W.—Surgical Scholarship. £350.

Barrow-in-Furness County Borough.—M.O.H., &c. £900.

Belfast, Joint Nursing and Midwives' Council, Northern Ireland.—Medical Examiners.

Belfast, Royal Maternity Hospital.—Res. M.O. At rate of £52.

Birmingham Children's Hospital.—Res. Surg. O. £175. Also H.P., H.S., and Cas. H.S. Each at rate of £75.

Birmingham, Dudley-road Hospital.—Jun. M.O. At rate of £200.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Sen. Asst. M.O. £750.

Birmingham, West Heath Sanatorium.—Res. Asst. M.O. At rate of £250.

Bolton, Royal Infirmary.—H.S. £125.

Bradford Royal Infirmary.—H.S. At rate of £135.

British Postgraduate Medical School, Shepherd's Bush.—Anæsthetist. Also 1st Asst. in Dept of Medicine. Each £300 Also 2 H.S.'s.

Cambridgeshire County Council.—Asst. County M.O. £500.

Cancer Hospital, Fulham-road, S.W.—Surgeon.

Canterbury, Kent and Canterbury Hospital.—2 H.S.'s. Each at rate of £125.

Cardiff, King Edward VII. Welsh National Memorial Association. Sen. Asst. Res. M.O. £350. Also Asst. Res. M.O. £200, for North Wales Sanatorium.

Chester, East Lancashire Tuberculosis Colony, Barrowmore Hall, Great Barrow.—H.P. At rate of £150.

Chester, Royal Infirmary.—H.P. also H.S. Each £150.

Chorley, Lancs, Chorley and District Hospital.—H.S. At rate of £150.

Colchester, Essex County Hospital.—H.P. Also Asst. H.S. £150 and £120 respectively.

Colonial Medical Service.—M.O.'s. Each £660.

Derbyshire Hospital for Sick Children.—Res. H.S. At rate of £130.

Devonport, Prince of Wales's Hospital.—H.P and Cas. O. At rate of £100.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts., Cas. H.S. Also H.S. Each £175.

Dreadnought Hospital, Greenwich, S.E.—H.S. At rate of £110.

Eastbourne, Princess Alice Hospital.—Res. H.S. £150.

Evelina Hospital for Sick Children, Southwark, S.E.—H.S. At rate of £120.

Exeter City.—Deputy M.O.H. and Asst. Tuber. O. £600.

Gloucestershire, Royal Infirmary.—2 H.S.'s Each at rate of £150.

Golden-square Throat, Nose, and Ear Hospital, W.—H.S. At rate of £100.

Great Yarmouth General Hospital.—H.S. £140.

Hampstead General and N.W. London Hospital, Haverstock Hill, N.W.—H.P. Also Cas. Surg. O. At rate of £100.

Harrogate Royal Bath Hospital.—Res. M.O. £156.

Hospital for Consumption and Dis. of Chest, Brompton, S.W.—Res. M.O. £350.

Hospital for Sick Children, Great Ormond Street, W.C.—Med. Reg. £300.

Hull Royal Infirmary.—H.P. for Sutton Branch Hospital. At rate of £160.

Huntingdon, Wyton Sanatorium.—H.P. At rate of £150.

Ilford Borough.—Asst. M.O.H. £600.

Ipswich, Mental Hospital.—H.P. £150.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. and H.S. Each £120.

Iraq Government, Basrah Port Health Services.—M.O. 70 Dinars a month.

Jersey General Hospital and Poor Law Infirmary.—Asst. Res. M.O. At rate of £150.

King Edward Memorial Hospital, Ealing.—Jun. Res. M.O. At rate of £150.

King's College Hospital, S.E.—Registrar to Ear, Nose, and Throat Dept.

Kingston-upon-Hull, Beverley-road Institution.—Two Asst. M.O.'s. Each £350.

Lancaster Royal Infirmary.—Jun. H.S. At rate of £130.

Leigh Infirmary, Lancs.—Sen. Res. H.S. Also Jun. H.S. At rate of £175 and £150 respectively.

Lincoln County Hospital.—Jun. H.S. At rate of £150.

Liverpool. Bootle General Hospital.—H.P. Two H.S.'s. Also Cas. O. Each at rate of £150.

Liverpool, Hahnemann Hospital, Hope Street.—Res. M.O. At rate of £120.

Liverpool, Stanley Hospital.—H.P. and 3 H.S.'s. Each at rate of £100.

Llanelly and District Hospital.—Hon. Part-time Radiologist.

L.C.C.—Asst. M.O.'s. Each £170.

London Skin Hospital, Fitzroy-square, W.—Hon. Physician.

Macclesfield, General Infirmary.—2nd H.S. At rate of £150.

Manchester, Ancoats Hospital.—H.S. At rate of £100. Also Orthopædic H.S. At rate of £100.

Manchester, Crumpsall Hospital.—Two Res. Jun. Asst. M.O.'s. Each at rate of £200.

Manchester, Monsall Hospital for Infectious Diseases.—Jun. Res. Asst. M.O. At rate of £250.

Manchester Royal Infirmary.—Res. Cas. O. At rate of £150. Also Sen. H.S. for Central Branch, Roby-street. £150.

Manchester and Salford Hospital for Skin Diseases.—H.S. At rate of £150.

Montrose Royal Asylum.—Jun. Asst. M.O. £300.

Newcastle-upon-Tyne Hospital for Sick Children.—H.P. and H.S. Each at rate of £100.

Nottingham, Children's Hospital.—Res. H.S. At rate of £150.

Nottingham General Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £150.

Nottinghamshire, C. C. Education Committee.—Asst. School M.O. £500.

Oldham, Boundary Park Municipal Hospital.—Res. Asst. M.O. At rate of £200.

Plymouth, Prince of Wales's Hospital, Greenbank Road.—Asst. H.S. At rate of £120.

Portsmouth City.—Tuber. O. and Sen. Asst. M.O.H. £750. Also Asst. M.O.H. and First Res. Med. Asst. £600–£750. Also Asst. M.O.H. and Second Res. Med. Asst. £500–£700.

Preston and County of Lancaster, Royal Infirmary.—H.S. for Special Depts. At rate of £150.

Queen Mary's Hospital for the East End, E.—Two Cas. and Out-Patient Officers, Each at rate of £150.

Queen's Hospital for Children, Hackney-road, E.—H.S. and Cas. O. Each at rate of £100.

Radium Beam Therapy Research, Radium Institute, 16, Riding House Street, W.—Asst. M.O. At rate of £250

Reading, Royal Berkshire Hospital.—Cas. O. and H.S. Each at rate of £125.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Naval Medical Service.—Nine M.O.'s.

Ryde, Isle of Wight County Hospital.—Res. H.S. £180.

St. Albans, Middlesex Colony for Mental Defectives, Harper-lane, Shenley.—2nd Asst. M.O. £460.

St. Bartholomew's Hospital, E.C.—Asst. Administrator of Anæsthetics.

St. Helens C.B.—Asst. M.O.H. £600.

St. Peter's Hospital, Vallance-road, Whitechapel, E.—Res. Med Supt. £950.

St. Thomas's Hospital.—M.O. in charge of Physio-Therapeutic Dept.

Sheffield, Children's Hospital.—H.S. At rate of £100.

Sheffield, Royal Infirmary.—Ophth. H.S. At rate of £120. Also H.S. and H.P. Each at rate of £80.

Southend-on-Sea, General Hospital.—Obstet. Officer. £125.

South Shields County Borough.—Asst. M.O. £500.

Stafford. Standon Hall Orthopædic Hospital.—H.S. £200.

Stamford, Rutland and General Infirmary.—H.S. At rate of £250.

Stockport County Borough.—M.O.H. £1100.

Stoke-on-Trent, Longton Hospital.—H.S. £160.

Sutton, Sutton and Cheam Hospital.—Asst. Res. M.O. At rate of £150.

Torqu [illegible] 5.

West [illegible] H.P. At rate of £200.

West [illegible] 73, *Welbeck Street, W.*—Hon. Med. Psychologists for Child Guidance Unit. Also 2 Hon. Clin. Psychologists.

Wigan, Royal Albert Infirmary and Dispensary.—H.S. At rate of £150.

Willesden General Hospital, Harlesden-road, N.W.—Res. Cas. O. At rate of £100.

Wolverhampton Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

Woodside Hospital, Muswell Hill, N.—Res. H.P. At rate of £100.

Woolwich and District War Memorial Hospital, Shooters Hill, S.E. Res. M.O. £175.

Worcester Royal Infirmary.—H.P. Also Jun. H.S. At rate of £160 and £120 respectively.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Oxted, Surrey.

Births, Marriages, and Deaths

BIRTHS

HARRIS.—On June 22nd, at Clifton, Bristol, the wife of H. Elwin Harris, F.R.C.S. Eng., of a daughter.

MACDONALD.—On June 26th, the wife of A. Robertson Macdonald, M.B., B.S. Lond., of Queen's Club-terrace, W., of a daughter.

MAURICE.—On June 23rd, at Savernake Hospital, the wife of James Maurice, M.R.C.S. Eng., of Marlborough, Wilts, of a daughter.

MARRIAGES

WIGLEY—BARNARD.—On June 25th, quietly, in London, John Edwin Mackonochie Wigley, M.B., B.S. Melb., to Evelyn Barnard, daughter of Mr. and Mrs. Stanley Hoare, of Cornwall-terrace, N.W.

DEATHS

PEACHEY.—On July 7th, at 16, Hillersdon-avenue, S.W., Dr. George Peachey.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

SUSSEX EYE HOSPITAL.—On July 2nd the new buildings of this hospital in Eastern-road, Brighton, were opened by Princess Victoria. They were erected at a cost of £40,000, and they consist of four wards of 10 beds each, eight private wards for paying patients, eight children's cots, and accommodation for the nursing staff.

NOTES, COMMENTS, AND ABSTRACTS

PRESSURE ON URETER BY ECTOPIC TESTIS

ALTHOUGH cryptorchidism in young adults is said to have an incidence of between 0·1 and 0·2 per cent., ectopic testis in the true sense of the term occurs much less frequently. Still less frequently does an ectopic testis give rise to symptoms in the urinary tract. Dr. George C. Prather describes such a rare case in the *New England Journal of Medicine* of March 7th, 1935. The patient, aged 27, was admitted to hospital complaining of a dull pain in the left flank of four years' duration. Abdominal examination revealed an enlarged left kidney, and an intravenous pyelogram confirmed the fact that there existed a left hydronephrosis with a tremendous dilatation of the left ureter. It was noted that the left side of the scrotum was empty. An extraperitoneal exploration of the kidney and ureter was carried out. On dissecting the ureter down to the bladder it was found that it became abruptly narrowed at the point of the crossing of the vas deferens, and on deep palpation a lump corresponding to the left testis was found lying against the posterior wall of the bladder. Since the hydronephrosis and hydro-ureter were badly infected, a nephro-ureterectomy was performed. Convalescence was uneventful and the patient was discharged free from pain 16 days after operation.

A NEGLECTED TONIC: CHARCOT'S BATH

Dr. T. PAGAN LOWE writes to suggest more general use of the form of physical treatment known as Charcot's bath. It requires, he points out, no special apparatus, for it consists merely in standing ankle deep in hot water and sponging the body locally six times. The cold sponge is applied once to each hip, then once to each shoulder, and finally to the chest and back, being followed by quick drying and brisk rubbing with a rough towel. "The bath," Dr. Lowe says, "should be taken on getting up in the morning and again the last thing at night. The rapidity with which it will contract up a dilated heart after influenza is astonishing—a fact which can be observed by anyone who cares to try it. I have seen good results many times, but one case, perhaps, may suffice by way of illustration.

A distinguished physician, after an influenzal attack, thinking his liver wanted exercise, went for a walk up a long and steep hill and thus produced an acute and extensive dilatation of his heart. When I saw him he had been treating himself by rest, two-hourly nourishment and heart tonics without any appreciable benefit, and, to use his own expression, he thought he was done for. Like many other medical men he had never heard of a Charcot's bath, but put it into use forthwith and made a rapid recovery.

The late Dr. Thomas Glynn, of Liverpool, whose house physician I was, and who brought this bath to my notice, gave it as his opinion that for nervous cases and as a general tonic this bath was the best treatment he knew. I have found it also useful in certain cases of insomnia of nervous origin even when an acute anxiety was known to be in operation. To get the best results, however, the bath must be properly administered. Simple though it be, many patients, particularly women, accustomed to the morning hot bath, require to be given it by a nurse for some days before they gain courage to give it themselves."

NURSING OF COLOTOMY

Miss KATE MAXEY, S.R.N., writes (from Bishop Auckland, Durham): Here is a practical hint for the nursing of a colotomy case. From experience I have found that a level teaspoonful of Epsom salts in warm water, followed by a cup of tea, acts after an interval of 40–45 minutes. A bed-pan is contrived consisting of a basin four inches deep and about six inches wide, covered with grease-proof paper fastened with a rubber band. A hole is cut at the centre of the paper large enough to take the colotomy, and the basin is placed at the centre of an air cushion inflated to a depth as great as that of the basin. The patient is then turned on his side over the central hole and kept in this position for three-quarters of an hour. This treatment I have found minimises the unpleasantness for the patient, and also saves soiled bandages, dressings, and garments.

THE VACCINATION QUESTION IN GERMANY

IN his capacity of Reichsärzteführer, or leader of the doctors of Germany, Dr. Wagner has issued a statement pointing out that the Government has hitherto refused to alter the present regulations concerning vaccination, which accordingly remain in force. It is not permissible to criticise the measures that the Government has seen fit to take, nor to stir up opposition to the regulations. "Therefore I rule," he says, "that the vaccination question shall not be discussed in medical and other technical periodicals." (Deut. med. Woch., July 5th, 1935, p. 1094).

THE "KLIPPON" GLARE SHIELD

THIS device, manufactured by Messrs. Theodore Hamblin Ltd., 15, Wigmore-street, London, is designed for the prevention of glare and consists of two dark celluloid shields, joined by a piece of elastic, which are made to clip on to ordinary spectacles. The shields are obtainable at all opticians, price 1*s.* 6*d.*

Medical Diary

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
TUESDAY, July 16th.—5.30 P.M., General Meeting of Fellows.

ASSOCIATION OF CLINICAL PATHOLOGISTS.

ADDRESSES AND ORIGINAL ARTICLES

CHRONIC DUODENAL ILEUS IN INFANCY AND CHILDHOOD

BY REGINALD MILLER, M.D., F.R.C.P. Lond.
PHYSICIAN TO ST. MARY'S AND PADDINGTON GREEN CHILDREN'S HOSPITALS, LONDON; AND

H. COURTNEY GAGE, M.R.C.S. Eng.
RADIOLOGIST TO ST. MARY'S HOSPITAL

(WITH ILLUSTRATIONS ON PLATE)

DURING the last six years we have been interested in the occurrence of chronic duodenal ileus from arterio-mesenteric compression as a cause of symptoms in early life, and we have published in a specialist journal[1 2 3] details of some of our cases with the evidence—radiographic, operative, and post mortem—on which the diagnosis was based. It is proposed here to give an account of the conclusions which we have sought to establish.

In 1929, when we encountered our first case at an operation on a young child, perusal of the literature brought out the following points of interest in connexion with chronic duodenal ileus in early life:—

(1) Chronic duodenal ileus, established as a comparatively rare condition in adults, is regarded as having two causative factors: first, a congenital anatomical factor, the compression of the duodenum by the root of the mesentery and (usually) the superior mesenteric artery; and secondly, an accessory factor of visceral distension or ptosis whereby the pressure on the duodenum is increased. The congenital factor has had to be assumed; otherwise it would be difficult to understand why visceral distension or ptosis should not always produce duodenal obstruction.

(2) Surgeons investigating their cases of chronic duodenal ileus in adults have found that there is frequently a history of vomiting and dyspepsia in childhood, which symptoms tend to pass off in late childhood or adolescence, to reappear in later life. D. P. D. Wilkie[4] in 1927 laid stress on this interesting point which was confirmed by R. P. Rowlands[5] in 1933.

(3) Arterio-mesenteric compression has occasionally been recorded as a cause of symptoms in young children, and in 1930 we were able to collect from the literature 8 cases between the ages of nine days and four and a half years. In these vomiting of bile had been a conspicuous feature, and the duodenum had been greatly enlarged (megaduodenum), so much so that in some it was visible under the abdominal wall and appeared like "a second stomach." In these two particulars the reported cases differ from those we have met, though it is possible that the difference between the two groups is merely one of degree. In our cases, even in infancy, the vomiting of bile is a rarity, and the duodenum, although enlarged, cannot fairly be described as a gross megaduodenum.

(4) Apart from this group, mainly giving rise to symptoms in infancy, there are very few references to the occurrence of chronic duodenal ileus in early life. A few isolated cases have been reported, but in most details were lacking and in many there were associated malformations or pathological lesions. We collected these cases in 1930.[1]

PRESENT INVESTIGATIONS

In December, 1928, there came under our care a small boy nearly three years old, of such frailty that he weighed only 19½ lb. His symptoms dated from birth, and careful clinical and radiographic examination led us to conclude that there was some obstruction to the evacuation of the stomach—almost certainly not in the stomach itself—which came into play chiefly, if not only, when the stomach was distended. Operation in May, 1929, revealed clearly compression of the duodenum by the root of the mesentery. The clinical history and features of this case were so peculiar that with the clue provided by this operation we were able to recognise milder cases of the same type, and in 1930 we published 9 of them under the title of "gastromegaly and chronic duodenal ileus in children." The term "gastromegaly" was used partly to emphasise the enlargement of the stomach which is the most striking sign in these cases, and partly as a group name because, as only 2 had been verified by operation, we were not sure then that the cause of the obstruction was the same in all. Now that with further experience it seems that the syndrome we described is always due to the same cause, the term "gastromegaly" appears unnecessary although it has become known amongst pædiatric physicians.

In studying these cases in young children we noted that, although typically the most prominent symptom in the earliest weeks of life was refusal of food (congenital anorexia), in a few instances vomiting had developed so soon after birth as to give rise to a suspicion of hypertrophic pyloric stenosis. In May, 1931, we met our first neonatal case in a girl of five days of age. Here although we were able to prove the presence of an incomplete duodenal obstruction, so severe was the vomiting that we failed to consider the possibility of arterio-mesenteric compression, which was revealed at autopsy on the eighth day. Since then, however, we have been able to recognise two other neonatal cases which have progressed well under appropriate medical treatment.

SYMPTOMS, SIGNS, AND RADIOGRAPHY

Symptoms.—As has already been mentioned the gastric symptoms are produced by two factors: the congenital anatomical factor of compression which persists in some degree until at least later childhood; and the accessory factor of gastric distension. The influence of the accessory factor must not be underestimated; it is the cause of the more urgent obstructive symptoms, even in the neonatal cases. Where gastric distension is avoided the stomach seems to become, as it were, compensated by hypertrophy and able to overcome the persistent congenital compression of the duodenum. It is important to realise that in early life gastric distension in these cases depends almost entirely on the amount of food taken, though the degree of gastric stasis no doubt plays its part; and this is the explanation of the fact that the earliest symptoms may consist either of refusal of food or of obstructive vomiting.

Symptoms can usually be traced back to the time of birth, but as in other congenital conditions there are exceptions to this rule. In the majority of cases the chief early symptom is complete lack of appetite; the child does not want its feeds, takes very slowly, and never finishes its bottles. Occasional small vomits may occur, but for the most part the underfeeding keeps the vomiting in abeyance. Progress is naturally slow, but the baby is looked upon as peculiar rather than ill, and no suspicion of any form of obstruction is aroused. At about the age of eighteen months, when the child is taking a mixed solid and fluid diet and can be pressed to take more than it wants, bouts of vomiting begin. In a smaller group of cases vomiting is an early symptom. We have already mentioned that in some of our cases seen at a later age there was a history of suspected hypertrophic pyloric stenosis in the early weeks of life, but in 2 out of the 3 neonatal cases which we have ourselves seen the vomiting was so severe and so obviously due to obstruction that a suspicion of congenital duodenal atresia was raised.

In either of these two groups the vomiting of obvious bile is exceptional. Even in the neonatal cases this is true, and only gastric lavage showed traces of bile in our cases.

Seen after the age of infancy—and most of our cases came under observation between the ages of two and eight years—these children are frail and underweight, but not notably stunted in height. It is rather characteristic that their complexions are pink and clear, showing neither the muddy skin of the intestinal dyspeptic nor the pallor of cœliac disease. Their chief symptoms are persistent lack of appetite and periodic attacks of vomiting. The anorexia is severe and is little influenced by purges, treats, or holidays. The frequency of the vomiting attacks depends greatly on what amount of food the child is made to take. The vomit shows accumulated food and mucus, and the attack is accompanied often by high fever and followed by diarrhœa with sometimes an excess of sodden mucus in the stools. A further rather characteristic symptom is hiccup, though its presence is seldom referred to by parents spontaneously. It is produced by a moderate degree of gastric distension and may be a warning of an attack of vomiting. Its disappearance under treatment is one of the earliest signs of improvement. The tongue is habitually coated, and the breath tends to be offensive.

As regards the bowels, constipation is not as prominent a symptom as might be expected, and if the bowels are disordered it is usually towards diarrhœa. Probably the persistent chronic gastritis readily sets up an enteritis. In some instances, especially in the younger children, the stools may contain much thick, sodden, and bile-stained mucus, which probably originates in the stomach. An excess of fat may appear in the stools from time to time, and we have had fat analyses as high as 59 per cent. of the dried fæces. Although such steatorrhœa is exceptional and always transient, it is worth bearing in mind in connexion with both diagnosis and treatment. It is presumably due to some interference with the flow of bile behind the duodenal obstruction. In several of our cases an opaque meal showed the colon to be unduly voluminous.

In 2 of our cases the intestinal symptoms have been much more in evidence than the gastric, and the child has suffered more from diarrhœa than from vomiting.

As will be seen from this account of the symptoms, although the past history may be rather characteristic, the symptoms themselves do not point at all clearly to any form of organic obstruction.

Physical signs.—The most characteristic physical sign is the protuberance of the upper abdomen from the enlarged and hypertrophied stomach (gastromegaly). This is best seen when the child is lying down but is often obvious in the upright position. The outline of the stomach may be clearly visible, and after a meal or draught of soda water gastric peristalsis may be observed in a good light. On palpation the wall of the stomach may give the sensation of being thickened, and gastric splashing may be elicited at any time.

Radiographic examination by means of an opaque meal has many uses in cases of chronic duodenal ileus. In severe neonatal cases it serves to distinguish between complete and incomplete duodenal obstruction. In milder instances at any age, where the presence of any form of obstruction may be doubtful, it serves to establish it by demonstrating gastric hyperperistalsis combined with delayed emptying-time of the stomach. It fairly easily excludes the pylorus as the site of the obstruction and this of itself tends to incriminate the duodenum. With careful technique the duodenal cap may be seen to fill easily and be enlarged, and with perseverance stasis in the lower part of the duodenum may be caught, although this cannot be guaranteed at any single examination. With good fortune the wall of the stomach may be seen to be definitely hypertrophied.

In order to get the best results two points require attention. First, the volume of the opaque meal must be considerably greater than that normally used for the age of the child; otherwise the enlarged stomach will be imperfectly filled and even delayed emptying-time may be missed. Secondly, it is much easier to get good views of the duodenum if gross gastric dilatation has been relieved by previous treatment. In the neonatal cases the meal should be given directly after the stomach has been washed out. Oblique and lateral views should be used to study the duodenum.

If the opaque meal is given before treatment has been instituted a peculiar picture is often seen. The stomach is much enlarged and stretches across the abdomen obliquely, almost ovoid in shape and projecting so far to the right as to hide the pylorus and duodenal cap completely even in oblique views. Very little is seen in the way of peristalsis and only small quantities of the meal pass on into the jejunum. This picture, although very characteristic to those familiar with it, cannot be taken to prove the presence of duodenal obstruction. It is essential that the duodenal cap should be seen at some part of the examination in order to demonstrate a normal pyloric canal with no increase in the pyloro-duodenal gap. If the meal is repeated after treatment has restored something of the gastric tone, the stomach, although still greatly enlarged, is more normal in outline, and in oblique views the duodenal cap is seen to be well filled and enlarged. Stasis in the lower parts of the duodenum as it runs to the middle line may be seen, and gastric hyperperistalsis and stasis, the combination typical of obstruction to the evacuation of the contents of the stomach, will certainly be seen.

DIAGNOSIS AND TREATMENT

It will be convenient to discuss these subjects in the two groups of cases, neonatal and later, separately.

1. *Neonatal group.*—In the cases seen in the first few weeks of life the differential diagnosis depends on the severity of the obstruction symptoms, and this in turn seems to depend at least as much on the distension of the stomach as on the persistent compression of the duodenum with which the child is born. If obstructive vomiting is present from birth the case will simulate one of congenital duodenal stenosis or atresia; if it develops later it may be mistaken for one of hypertrophic pyloric stenosis, pylorospasm, or non-obstructive dyspepsia. Our 3 neonatal cases show these differences well; we give them in the order in which we met them.

Case 1.—Female; vomiting from birth; seen 5th day. Opaque meal showed large stomach passing only minute quantities of meal into small jejunum. Vomit showed much mucus but no obvious bile. Operation on 7th day: stomach large, duodenum large; cause of obstruction not recognised. Autopsy on 8th day revealed arterio-mesenteric compression.

Case 2.—Female; vomiting from birth; seen 10th day. Stomach large; vomit projected, containing much mucus but no obvious bile. Immediate opaque meal showed dilated lower œsophagus, with large ovoid stomach emptying very little food into jejunum. In the hope of duodenal ileus operation was postponed and gastric lavage ordered. First lavage stopped all serious vomiting; first two washings showed traces of bile. On 16th day second opaque meal showed large stomach with improved tone and emptying-rate, and obvious duodenal stasis (Fig. I. on Plate). Progressed well. At 5 months (weight, 17½ lb.) visible gastric peristalsis still present. Third opaque meal showed stomach emptying well by hyperperistalsis, and duodenal stasis again seen. At 12 months reported progressing well.

Case 3.—Female; vomiting from birth slight, but severe after first three weeks; seen aged 8 weeks. Stomach large, peristalsis visible, vomit projected and containing much mucus but no obvious bile. Immediate opaque meal showed large ovoid stomach with stasis; barium vomited 10 hours after ingestion. Lavage showed traces of bile. At 11 weeks second opaque meal showed stomach emptying more quickly. At 12 weeks third opaque meal given immediately after lavage showed duodenal stasis. Progress satisfactory. At 6 months (weight, 12½ lb.) died of diphtheria. Autopsy confirmed presence of arterio-mesenteric compression.

In cases where severe vomiting dates from birth it may be difficult except by radiography to exclude duodenal obstruction from congenital malformation of the duodenum. In nearly all instances of this condition the obstruction is complete, and if the opaque meal discovers that the obstruction is incomplete we would urge that operation be postponed for one or two days to try the effect of gastric lavage. In our experience the commonest cause of a congenital incomplete duodenal obstruction is arterio-mesenteric compression. Partial obstruction by bands has been reported as a great rarity, but there is reason to think that in some instances such bands have been merely complicating arterio-mesenteric compression.

Where obstructive vomiting appears in the first few weeks of life rather than at birth, pyloric stenosis can be readily excluded. Pylorospasm is a painful condition and mucus is not vomited. Non-obstructive dyspepsia should be excluded by the enlargement of the stomach, the presence of visible gastric peristalsis, and the obstructive type of vomiting in which the vomit is copious, projected, and containing excess of mucus. The use of an opaque meal will confirm the presence of obstruction.

Three points in diagnosis require emphasis. First, the absence of obvious bile in the vomit does not preclude the presence of chronic duodenal ileus. Secondly, the persistent presence of an excess of mucus in the vomit in a chronic case of vomiting in a young infant signifies obstruction at the pylorus or in the duodenum. Thirdly, to get the best results in the use of an opaque meal the meal should be large and given directly after the stomach has been thoroughly washed out.

As regards treatment in the neonatal cases, gastric lavage seems quickly to stop serious vomiting by restoring the tone of the distended stomach and reducing its emptying-time. For this purpose a dilute solution of sodium bicarbonate probably deals better with the mucus in the stomach than normal saline and appears quite harmless. Lavage should be given at first every 12 hours, and when the washings become clear the intervals may be increased to 24, 36, and 48 hours. Lavage every two or three days will probably be needed for about three months. Distension of the stomach or large projected vomits are indications for more frequent lavage. The feeds should be spaced by the emptying-time of the stomach which is easily estimated in a small infant by passing a tube four hours after a meal. It should be borne in mind that under treatment the emptying-time of the stomach quickly improves.

2. *In late infancy or early childhood.*—The chief difficulty in diagnosis here is to recognise the possibility of the presence of any obstructive factor in the production of the symptoms. In only 2 of our cases had any investigations on these lines been made before they came under our care. On the other hand in several instances the mother had observed the peculiar protuberance of the child's upper abdomen and had tried to interest the doctor in this phenomenon. Apart from the fact that the history may date from birth or early infancy, the symptoms of lack of appetite and attacks of vomiting will hardly allow the child to escape the label of "acidosis." Perpetual hiccup, if inquired for, is suggestive. The diagnosis must be made on the clinical and radiographic signs; the enlarged protruding stomach, the visible peristalsis, and the persistent splashing suggest stasis and obstruction, which can be confirmed by the evidence given above afforded by the use of an opaque meal.

Treatment by medical measures is not unsatisfactory. In the younger children a certain degree of underfeeding may be unavoidable, but in the older children, who are already beginning to improve spontaneously, progress may be quite dramatically successful. Bearing in mind the importance of the volume of the feeds and the tendency to gastric stasis, it is essential to separate the fluids from the solid food as far as is possible and to give meals well spaced apart. A mixed diet, slightly low in fat, should be given mainly minced and as dry as may be palatable, and drinks should be given about three hours after meals. A mixture containing ½-drachm doses of glycothymolin (K. and O.) with rhubarb and soda is very useful in the early stages. Later, hydrochloric acid drinks may be allowed with meals. Paraffin should be avoided as an aperient. Massage and ultra-violet light may be a help.

Although the amount of exercise allowed may have to be curtailed to suit the subnormal intake of food, it is unwise to keep these children entirely in bed for any length of time. Exercise and fresh air help their digestions.

As regards the possibility of relieving the duodenal obstruction by operation, in the neonatal cases the risk is so extreme that medical treatment should at least be given a trial. In the older children it must be clearly understood that the enlargement of the duodenum is not sufficient to render the operation of duodeno-jejunostomy a possibility. Gastro-jejunostomy has not been found a success in adult cases of chronic duodenal ileus, and from our experience of 2 cases in children it is a disappointment in them also. The indications are to be satisfied with slow improvement rather than to resort to operation.

In the cases showing gross megaduodenum, which we have mentioned but have not met, duodeno-jejunostomy would presumably be the correct procedure.

PROGNOSIS AND COURSE.

In our 2 neonatal cases in which gastric lavage was employed improvement was dramatic. By treating the accessory factor of gastric distension satisfactory progress was made in spite of the persistence of the congenital obstruction. That all cases would show similar improvement is perhaps doubtful, but in both our cases the obstruction appeared severe.

In cases seen at a later age treatment tends to stop the vomiting attacks, but in the younger children progress may be slow as it may be difficult to get a normal amount of food tolerated by the stomach. In children of eight or ten years old, in whom spontaneous improvement is to be expected, the effect of treatment may be a great success.

As Wilkie pointed out, there is a tendency towards spontaneous improvement in later childhood. This seems to take place at about the ages of eight or ten, and is probably due to the growth of the child. These children therefore, unlike most cases of cœliac disease, will be able to get to preparatory boarding schools. But we are by no means sure that all attain to complete freedom from symptoms. We suspect that some examples of severe gastric dilatation seen at puberty or in adolescence derive from congenital duodenal ileus, and we have had one such case under our care at the age of seventeen years who developed acute duodenal ileus following laparotomy fifteen years later. During childhood this post-operative complication seems practically unknown, and several of our patients have been through operations for the removal of tonsils or appendix without untoward results.

SUMMARY

Chronic duodenal ileus arising from congenital arterio-mesenteric compression of the duodenum is described as a cause of obstructive symptoms (*a*) in the newly born, and (*b*) in later infancy and early childhood; and its symptoms, signs, diagnosis, course, and treatment are discussed.

CORTICAL CARCINOMA OF THE SUPRARENAL

WITH CUSHING'S BASOPHIL PITUITARY SYNDROME

BY DOROTHY C. HARE, C.B.E., M.D., M.R.C.P.Lond., D.P.H.
PHYSICIAN TO THE ROYAL FREE HOSPITAL
JOAN M. ROSS, M.D. Lond.
READER IN PATHOLOGY, UNIVERSITY OF LONDON; AND
A. C. CROOKE, M.D. Camb.
GROCER'S RESEARCH SCHOLAR, LONDON HOSPITAL

THE clinical signs characteristic of the syndrome, conveniently called basophilism, which has been attributed to basophil adenoma of the pituitary are now well known. The close parallelism between this syndrome and that regarded as being produced by hyperfunction of the suprarenal cortex in adult women has recently been emphasised. The following is the report on a case of carcinoma of the suprarenal cortex in which special investigation of the pituitary (A. C. C.) has led to the observation of cytological changes hitherto unrecognised. Briefly, the chief clinical symptoms and signs were attacks of severe headache and vomiting, and persistent metrorrhagia followed by amenorrhœa. Hirsutism, of the male type, with loss of scalp hair, greasy skin, an acneiform eruption, and striæ atrophicæ. These were associated with an adiposity of face, neck, shoulders, and trunk, and the limbs were slender. The patient developed kyphosis, and had polycythæmia and a raised blood pressure. At operation a malignant suprarenal tumour was removed and metastases were found at the post-mortem.

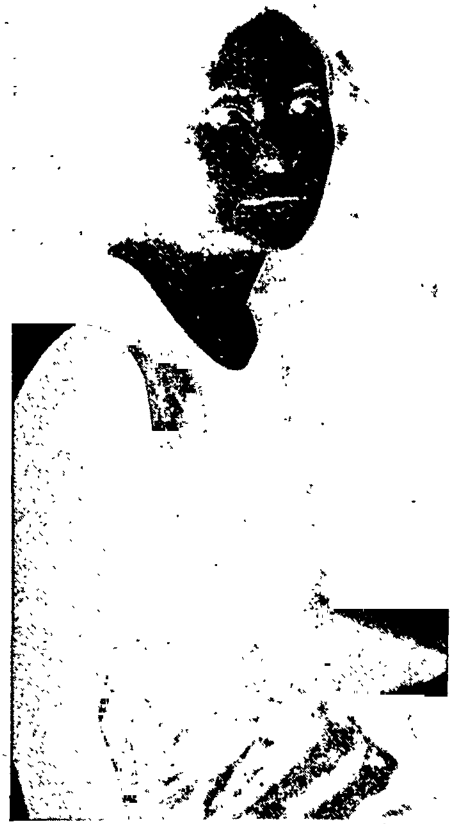

FIG. 1.—The patient at age of 24 (1926).

The patient, a machinist, was the tenth of a healthy family of twelve children. She was unmarried, the menses were regular, and she had had no previous illnesses of importance, and was in good health (Fig. 1) till November, 1931, when she missed two menstrual periods and began to be languid and sleepless. After an attack of tonsillitis in February, 1932, the menses became gradually prolonged, lasting up to six weeks, the daily loss not being at any time excessive; during 1933 the average duration was from seventeen to twenty-one days with irregular intervals; this was followed by amenorrhœa from February, 1934, interrupted by a slight menstrual discharge on May 24th and another in December, 1934; a slight brownish discharge was present at other times.

Changes in facial appearance were noticed early in 1933. The complexion, previously good, became spotty, the scalp hair broke off short, and the beard began to grow in April, 1933. The patient gained about half a stone in weight during 1933, and made a further gain of fourteen pounds during 1934. The maximum weight was 139 pounds. Headaches, to which she was always liable, increased in frequency, severity, and duration; vomiting was liable to occur on waking, or would follow the development of the headache. She complained of a sense of weight and discomfort in the epigastrium, particularly on walking, and was liable to attacks of giddiness. The appetite was very good but not excessive. Thirst was increased and nocturnal frequency of micturition occurred. She noticed no change in her voice. No history of hæmorrhages or bruising was obtained, except a slight hæmoptysis in January, 1934. Mentality and efficiency were unimpaired. The patient continued at work until December, 1934, except during the period between Feb. 6th and May 31st, 1934, when she was an in-patient at the Royal Free Hospital. During this period she was shown at a meeting of the clinical section of the Royal Society of Medicine.[1] She was kept under continuous observation during 1934, and progressive changes in her appearance were noted; though there was little change in the symptoms, she felt progressively less able to carry on her work.

Her physical condition did not change much between February, 1934, and December, 1934 (see Figs. 2, 3, and 4), when she presented a masculine appearance. She was 5 ft. 2 in. in height, florid, with rounded shoulders, kyphosis of the upper thoracic and cervical spine, short thick neck and double chin, heavy trunk and prominent abdomen with relatively slender limbs, hands and feet. The face and extremities were congested, and the lips a deep colour. The skin over forehead and cheeks was thick and coarse with few creases; it was greasy, and there was an acneiform eruption on face and back. The scalp hair was dark, short and curly, and brittle, and made hardly any growth; there was a tendency to baldness in the centre and over the temples, which had been exposed to X ray treatment. She had a reddish beard, clipped about once a week, which grew thickly below the chin and less profusely in the whisker and moustache areas. A line of hair extended from pubes to umbilicus, sparse hairs were present round the nipples, and excess of fine hair on the front of the thighs, but no excess of hair elsewhere on the limbs. The adipose tissue was distributed chiefly on the lower part of the face, neck, shoulders and trunk; the abdomen was prominent. Two purple striæ atrophicæ were present at this date; none were seen in February, 1934. The breasts were small and of the obese male type.

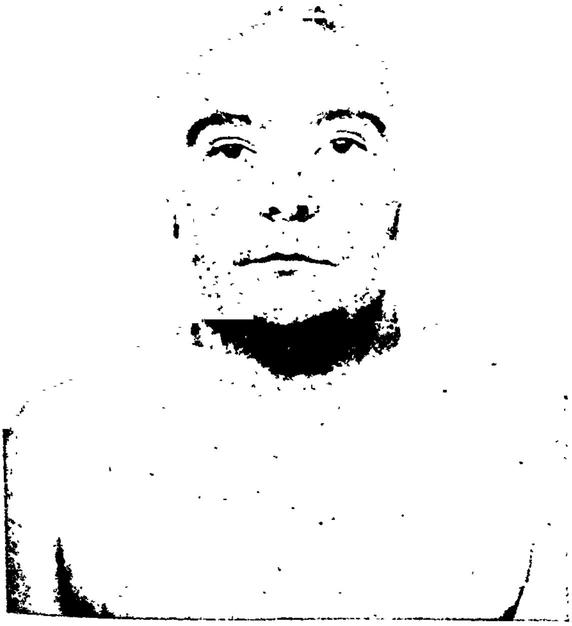

FIG 2.—The patient at age of 32 (March, 1934).

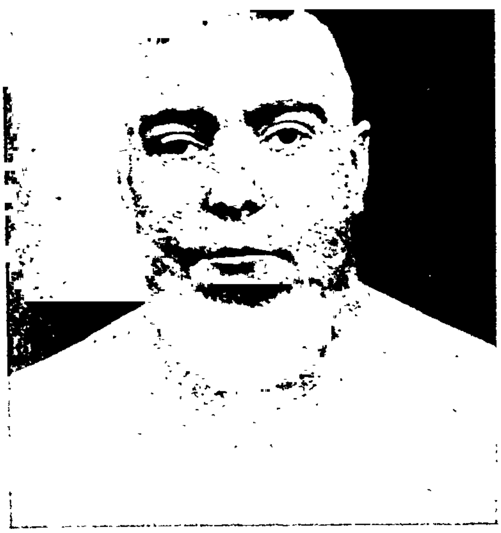

FIG. 3.—The patient in December, 1934.

The *heart* was slightly enlarged, the action forcible, and the sounds clear. The electrocardiogram showed a left-sided preponderance. The blood pressure was: systolic 205 mm., diastolic 140 mm. Hg on Dec. 29th. The abdominal wall was very thick and prominent, and the liver, spleen, and kidneys were not palpable; no tumour could be felt. The external genitalia were normal except for a slight enlargement of the clitoris. The cervix was small and soft and the uterus could not be defined. In lungs, urinary, and central nervous systems, nothing abnormal was found. The fundi were normal and the fields of vision and blind spot also normal.

Special investigations.—In February and March, 1934, the case was studied in detail. An X ray of the pituitary fossa showed it to be rather smaller than normal, the antero-posterior diameter being 11 mm. The outlines of the kidney (intravenous pyelogram) appeared normal and a skiagram of long bones, with control, showed no lack of Ca salts.

The Wassermann and Kahn tests were negative. Examination of urine gave a normal urea-concentration

which is stained a uniform greyish-blue by the modified Mallory method. The extent of this hyaline change shows great variations, which are apparently stages of a progressive involvement of the cytoplasm. In most of the cells the greater part of the cytoplasm is hyaline. In some of these the granular cytoplasm is reduced to a narrow zone in the extreme periphery of the cell body and also a demilunar or rounded area against the nucleus, which in the case of an eccentric nucleus lies against the side upon which the cytoplasm is most abundant. In others the granular cytoplasm is confined to one or other of these two sites. In many cells the entire cytoplasm is hyaline. A few medium or large vacuoles, similar to those often seen in normal ripe basophil cells, may be present in the hyaline cytoplasm. The remnants of granular cytoplasm are usually finely vacuolated. This vacuolation is especially conspicuous in remnants that form a rim round the cell. The nuclei of the affected cells show no sign of degeneration, and two or more nuclei are sometimes present. No mitoses were observed. The change was not found in the basophil cells in the posterior lobe.

TABLE II

Percentage of different cells in 94 normal adult non-pregnant females (Rasmussen, 1933)

Cell types.	Minimum.	Maximum.	Median.	Mean and probable error.	Standard deviation	Coefficient of variation.
Chromophobe	32·9	74·1	49·0	49·6 ± 0·47	6·79	14
Acidophil .	19·2	57·5	44·2	43·4 ± 0·56	8·10	19

TABLE III

Percentage of different cells in two cases of adreno-cortical syndrome

	Our case.	Lescher and Robb-Smith's case.
Chromophobe	49·78	31·5
Acidophil	45·81	50·25
Basophil	4·41	17·25

REMARKS

There is a marked discrepancy between the count of the percentages of different cells in the pituitary gland in this case and the count in the case of carcinoma of suprarenal cortex associated with an almost identical syndrome of basophilism which has been described by Lescher and Robb-Smith.[2] In the present case the percentage of basophil cells was within the normal limits and slightly above the minimum found by Rasmussen[4] in adult women. Lescher and Robb-Smith, on the other hand, in their case found a percentage slightly above the maximum of Rasmussen. It is, unfortunately, not possible to judge the extent to which the two imitations of the method of Rasmussen[3] give comparable results. The method employed in this case has been described in detail and its conformity to Rasmussen's method has been tested by a count of the gland from a normal man[5]; the percentages obtained were close to the modes found by Rasmussen[3] in 100 normal adult males. Prolonged deep X ray therapy had been directed to the pituitary fossa in this case, so that the possibility of this having reduced the number of basophil cells must be considered. There is, however, no evidence that X rays destroy basophil cells more than chromophobe or acidophil cells. Further, there is no evidence of degeneration of the basophil cells unless it be the hyaline change that has been described in the cytoplasm. Dr. Robb-Smith has kindly sent us a section of the pituitary gland from the case described by him with Dr. Lescher. No X ray treatment had been given in this case. The section, when stained by the Mallory method, shows exactly the same hyaline change in the basophil cells. The hyaline change cannot, therefore, be attributed to X ray therapy.

The occurrence of this hyaline change, its nature, and its significance in the syndrome of basophilism are discussed by one of us (A. C. C.) in another paper, which will shortly be published. The view will be put forward that it should be considered to be an expression of altered physiological activity and not a degeneration in the sense of a change leading to the death of the cell.

SUMMARY

A case clinically indistinguishable from the syndrome attributed to basophil adenoma of the pituitary gland is reported. A carcinoma of the suprarenal cortex was removed at operation and metastatic growth was found at autopsy. In serial sections of the pituitary gland no basophil adenoma was found. The differential cell count was within normal limits. A hyaline change in the basophil cells of the anterior lobe is described.

VENTRICULOGRAPHY BY OPAQUE INJECTION

BY E. W. TWINING, M.R.C.S. Eng., D.M.R.E.
ASSISTANT RADIOLOGIST TO MANCHESTER ROYAL INFIRMARY
LECTURER IN RADIOLOGY IN THE VICTORIA UNIVERSITY, MANCHESTER; AND

G. F. ROWBOTHAM, F.R.C.S. Eng.
CHIEF ASSISTANT IN THE NEUROSURGICAL SERVICE, ROYAL INFIRMARY, MANCHESTER

(WITH ILLUSTRATIONS ON PLATE)

NEUROLOGICAL surgery owes much to pneumography of the cerebral ventricles, introduced by Dandy, which in the hands of the expert neurological surgeon has been, and will doubtless continue to be, of inestimable value in the diagnosis and localisation of brain tumours.

There are, however, numerous difficulties in the interpretation of ventriculograms, largely due to the fact that it is only the "air shadow" which is differentiated in the radiograms from the surrounding brain tissue, whereas any residual fluid remaining in the ventricular system is not so differentiated. This residual fluid, lying in pools at the most dependent parts of the ventricles, often confuses the picture, for it may be impossible to say whether an abnormality of the ventricular contour is due to this fluid or to something in the brain tissue, or in the cavity of a ventricle.

In ventriculography by the method of air injection we are therefore reduced to two alternatives: we may either drain the ventricles very completely in order to obtain a complete "air-cast" of the entire ventricular system, or we may partially fill the ventricles with air, and then make a series of radiograms with the head in different positions, using the air bubble to explore successively the contours of different regions of the system. The latter is the method usually employed in Mr. Jefferson's clinic at Manchester Royal Infirmary, since it avoids the severe and often dangerous alterations in intracranial tension which may follow total air replacement. This "piecemeal" method involves numerous changes in the position of the patient, and the taking of a large number of films; the technique is somewhat exacting, and in order to outline the third and fourth ventricles the patient must adopt a position amounting to inversion of the head.

One of us (E. W. T.) has worked out a technique for this which has been described in a paper[1] read before the section of radiology, Royal Society of Medicine, in November, 1933, and in more elaboration in a paper before the Society of British Neurological Surgeons in November, 1934.

Although the methods just mentioned have afforded convincing data, certain difficulties connected with the interpretation of ventriculograms, usually due to pools of residual cerebro-spinal fluid, prompted the suggestion by one of us (E. W. T.) that a "double-contrast method" would be of considerable assistance. By "double-contrast method" is meant the introduction of a radiopaque diffusible material into the ventricles which would differentiate the fluid-filled part of the ventricles from the surrounding brain, as well as from the air introduced. Alternatively, it was foreseen that the diffusible material might be introduced instead of air, which would produce opaque ventriculograms, and would avoid the alteration of intracranial tension which accompanies air replacement. It was hoped that an image might be obtained of sufficient density to render possible satisfactory stereoscopic views of the ventricular system, since stereoscopic views of the *air*-filled ventricles are notoriously unsatisfactory, owing to lack of contrast.

Various substances were considered. *Lipiodol*, so commonly used for opaque injections of the spinal theca, was thought to be unsuitable because it is not miscible with cerebro-spinal fluid, but tends to collect into droplets. *Uroselectan* was next considered, and an attempt was made to render the intraventricular cerebro-spinal fluid opaque by injecting 5 c.cm. of this substance. The resultant shadow was of very unsatisfactory density. *Thorotrast* was then suggested (E. W. T.) as being suitable. This substance is frequently used for injection of the arterial system and has been injected in quantities of 60 c.cm. into arteries and veins, being non-toxic when so used. It later becomes deposited in the reticulo-endothelial system, chiefly of the liver and spleen. Preliminary experiment showed that it was readily diffusible in water and in cerebro-spinal fluid, and that a concentration of 1 in 8 would give a good radiographic shadow. It was therefore decided to use the method in the following case, in which there was evidence of cerebral tumour with conflicting localising signs—a case in which it was felt essential to obtain the utmost possible detail of the ventricular contours, while avoiding total ventricular drainage.

A CASE FOR INVESTIGATION

The patient, an engine driver aged 50, was a well-developed muscular man. His illness began abruptly on the evening of Feb. 13th, 1935, with a general headache, which became very severe, necessitating his going to bed, and rendering him incapable of going to work the next morning. Since that time he had suffered from severe generalised headaches, which came on every morning and lasted for a few hours. They were commonly associated with vomiting. There had not been any deterioration of vision, and from his wife it was ascertained that he had changed considerably, in that he had become drowsy and distant in his manner. There were no other symptoms.

On admission to hospital on April 2nd he seemed extremely drowsy, but on closer investigation it was found that usually he was not asleep, but rather disinterested in the surrounding activities of the ward. On being questioned he would answer slowly but quite rationally; he was not apathetic about his own condition, but very willing to coöperate. There was no aphasia or urinary incontinence.

He had a low-grade bilateral papillœdema, rather more obvious on the left side, but no other neurological signs apart from a slight fine nystagmus to the right, and an indefinite extensor plantar response on the left side. The Wassermann reaction was negative in the blood and cerebro-spinal fluid. A radiographic examination of the skull revealed no evidence of cerebral tumour, and the protein content of the cerebro-spinal fluid was 80 mg. per 100 c.cm., the normal being 25 mg.

A diagnosis of a cerebral tumour was made, but it could not be localised with precision, the suggestions being an intraventricular tumour (because of the high cerebro-spinal fluid protein content), a right frontal meningioma, or a tumour of the corpus callosum. A ventricular estimation was performed (G. F. R.) which proved: (1) that there was no lateral displacement of the ventricles; (2) that they were in communication; and (3) that they were dilated. Again sufficient evidence was not forthcoming to permit of localisation, and it was therefore thought necessary to make a ventriculographic examination. In view of the presumptive diagnosis of intraventricular tumour, a complete study of the outlines of the ventricles was desirable. Accordingly, in view of the man's condition, and of the risk attending total air replacement, it was decided to adopt the above suggestion of injecting a suitable amount of radiopaque diffusible substance.

THE METHOD AND ITS RESULTS

With the patient lying on the left side 25 c.cm. of fluid was withdrawn from the right ventricle, and 10 c.cm. of air was introduced, followed by 10 c.cm. of thorotrast. The thorotrast was poured into the funnel used for the reception of the cerebro-spinal fluid, and mixed with it by agitation. It was then run into the ventricles by raising the funnel. Radiograms were made within 15 minutes. Diffusion of the thorotrast had been completed by this time as the radiograms showed even density in both ventricles. The presence of opaque cerebro-spinal fluid in the left ventricle proved that the lateral ventricles communicated freely.

A complete series of ventriculograms was made. The patient's condition was good. He did not complain of the headache generally present when air replacement is employed. The pulse-rate was 100 and he was sweating rather freely; but his mental condition was undisturbed, he coöperated readily, and he had no toxic symptoms.

The success of the injection from a radiographic point of view was very gratifying (Figs. I.–III. on Plate). The ease with which the third ventricle was shown should be noted. This method necessarily succeeds in showing the third ventricle (if the foramina of Monro and the ventricular cavity are patent), because it is filled with cerebro-spinal fluid, mixed with the opaque medium. The 10 c.cm. of air which was introduced in this case collected for the most part in the uppermost ventricle in the lateral lying position, and in the frontal horns in the supine position, so that there was very little air in the third ventricle at any time. The contours of this ventricle were therefore very clearly delineated in all views. The fourth ventricle was also outlined.

In order to ensure filling of the third and fourth ventricles by opaque fluid, lateral films were also taken with the patient sitting up—thus reversing the technique we ordinarily use to fill it with air (inversion method). This is very simple, and gets over the difficulty which has attended the use of air ventriculography of the third ventricle; for in that procedure it is often difficult to get rid of all the fluid in the third ventricle, which tends to remain in the suprapineal recess at its posterior end, and therefore introduces an element of doubt into the interpretation of the ventricular contours. The new method eliminates this difficulty. It is the most dependent point of the ventricle which is shown as an opaque shadow, exactly as in a barium investigation of the *alimentary tract.*

THE RADIOGRAMS AND THEIR INTERPRETATION

The radiograms were of outstanding clarity and definition.

The lateral ventricles were slightly hydrocephalic. The right lateral ventricle showed a striking deformity: it was flattened from above downwards, and depressed below the level of the left. The deformity was most marked in the body of the ventricle, the frontal horn showing depression but less conspicuous deformation than the body. The right temporal horn was compressed from side to side and the right occipital horn flattened. The ventricles were not appreciably displaced from the mid-line. The foramina of Monro were *patent, and the third ventricle lay in the middle* line.

The lateral view showed a large rounded filling defect occupying the posterior two-thirds of the third ventricle; the aqueduct of Sylvius was compressed and distorted; the fourth ventricle outlined (though somewhat faintly, owing to the compression of the aqueduct).

Interpretation is extremely difficult. The flattening of the body of the right lateral ventricle on its upper side suggests a lesion of the corpus callosum. The possibility has to be considered that it results from a right temporal tumour, since it is well known that a temporal lobe tumour may cause this deformity by displacing the corpus callosum under the falx cerebri, so that the ventricle on the side of the tumour is lower than that on the opposite side.[2] But in this case there is no appreciable displacement; the cause of the flattening must therefore be above the ventricle, possibly in the corpus callosum itself.

The deformity in the posterior end of the third ventricle is very striking. If unaccompanied by any deformity of the lateral ventricles it would point to a pineal tumour, choroidal plexus tumour, or other tumour of the third ventricle. It is impossible on the radiograms to eliminate these, but in the presence of an associated deformity of the right lateral ventricle the possibility arises that the third ventricle deformity may be due either to (1) an enlargement near the posterior end of the corpus callosum, pushing the posterior contour of the third ventricle forwards; or (2) a bulging of one optic thalamus towards the mid-line.*

After the radiograms were made the patient was again taken to the operating theatre and 20 c.cm. cerebro-spinal fluid was removed from the ventricles. This was compared with test mixtures made up in test-tubes containing thorotrast and water. Mixtures of 1 in 2, 1 in 4, 1 in 8, 1 in 16, and 1 in 32 were radiographed in test-tubes of equal diameter together with the specimen of cerebro-spinal fluid obtained *from the patient's ventricles, all being included in a* single exposure. The radiographic density of the specimen was less than that of a mixture of thorotrast and water, 1 in 4, but greater than a mixture of 1 in 8. It was estimated as 1 in 6.

Further radiographic examination two hours later showed that almost all the thorotrast had left the ventricular system, only a faint shadow being now visible. It was not possible to say how much had been removed, and how much had leaked away into the spinal theca. Only a trace of air remained.

A second case of ventriculography by thorotrast injection is demonstrated in Fig. IV. This radiogram is a lateral view from a case of verified right-sided acoustic neuroma. It demonstrates clearly the normal *outline of the lateral and third ventricles and of the* aqueduct of Sylvius. The anatomical points depicted in the radiogram are illustrated in the line diagram, Fig. IV.*a*. The contour of the normal third ventricle in this radiogram should be compared with that of the deformed third ventricle in the first case (Fig. I.).

DISCUSSION

Other radiopaque substances have been used for ventriculographic examination, notably lipiodol (Sicard, Paraf, and Laplane, 1923). Balado has employed lipiodol since 1928, and Lysholm[3] has recently published an extensive review of that method. Lysholm refers to risks attending its use, especially in the presence of stenosis of the aqueduct and fourth ventricles.

It must be emphasised that lipiodol is not miscible with cerebro-spinal fluid. It is therefore only used in small quantities as an accessory to air replacement. It cannot be used for complete outlining of the ventricles. The method we describe, of using a substance which is freely miscible with cerebro-spinal fluid, offers considerable advantages. Radiographically the results surpass those of air injection in density and definition, and in the ease with which the whole ventricular system can be shown, not only in its main features, but also in its fine details. Stereoscopic views are extremely satisfactory.

From the point of view of the patient's well-being the method offers the great advantage that intracranial tension is unaltered, and that the not inconsiderable risk of air replacement (estimated by some authors to have a mortality of 10 per cent.) is obviated.

Our results were obtained with thorotrast, which from a radiographic point of view is adequate. Other workers have doubted the suitability of thorotrast to which they have ascribed irritative properties.

In four cases observed in this clinic for periods of up to three weeks between thorotrast injection and operation, there have been no alarming or serious symptoms. The immediate condition of the patients after injection compared extremely well with that of patients who have had air replacement. The latter usually complain of headache, often severe, and tolerate the necessarily lengthy and complicated X ray examination badly. By contrast, the patients who had thorotrast coöperated well in the examination, which caused them no inconvenience. Our general impression is that the immediate effects of thorotrast are milder than those due to air. We cannot yet claim that it is the ideal substance; it has been shown by Alexander,[4] in experimental work in the dog, to cause proliferation of the ependymal cells, which apparently become phagocytic to the thorotrast granules. This proliferation, which is also caused by oily substances (e.g., olive oil) might conceivably produce late effects. A longer time of observation is necessary for the full evaluation of end-results. We believe, however, that the method in principle is correct, and that it may supersede air replacement for the following reasons: (1) Complete outlining of the ventricular system is obtained with greater possibilities of precise interpretation. (2) It simplifies radiographic technique (3) Stereoscopic radiography is possible. (4) There is a minimum interference with compensated intracranial pressure, thus diminishing risk of tumour shift and hæmorrhage.

Our best thanks are due to Mr. Geoffrey Jefferson for permission to publish the cases described in this preliminary communication, and for his interest and coöperation.

VIRUS BODIES IN THE PERICARDIAL FLUID OF RHEUMATIC FEVER

AND OTHER CONDITIONS, AND IN THE JOINT FLUID OF RHEUMATOID ARTHRITIS

By Alfred C. Coles, M.D., D.Sc., M.R.C.P. Lond., F.R.S. Edin.

CONSULTING PHYSICIAN TO THE ROYAL NATIONAL SANATORIUM AND ROYAL VICTORIA HOSPITAL, BOURNEMOUTH

(WITH ILLUSTRATION ON PLATE)

In certain instances of infection where larger organisms cannot be found and the infective agent is unknown, close observation has revealed the presence of minute bodies that can be seen by appropriate illumination or stained by suitable procedures. In some cases the presence of specific antibodies such as agglutinins has been demonstrated for these "elementary bodies"; and in at least two examples—viz., vaccinia and psittacosis—further evidence has been forthcoming that the bodies in question are the actual virus of the disease, because when separated off by high-speed centrifuge and injected into animals they reproduce the disease.

For years past I have spent much time in searching for virus bodies in such material as I have been able to obtain from likely cases—e.g., vaccinia, varicella, herpes, molluscum contagiosum, psittacosis—and amongst other material I have now examined a considerable number of specimens of pericardial fluid for such bodies. In view of the interesting and promising results of Schlesinger and his colleagues[1] published in THE LANCET of May 18th on the elementary bodies in rheumatic fever, it has occurred to me that these observations, made quite independently of their work, may possibly be of some interest.

Methods.—Films were made from the exudate as thin as possible at one end and considerably thicker at the other end of a slide. These when dry were fixed in alcohol for about 5 to 10 minutes, and then stained in well-diluted Giemsa for 24 hours. At the end of 12 hours the stain was usually renewed. Although all virus bodies are clearly stained in 12 hours, preparations which had been subjected to the stain for 24 hours were preferred. When the stained films were quite dry I often found it advantageous to differentiate part of the smear by pouring a few drops of orange-tannin on half the film, and after allowing this to act for about 5 minutes, the whole slide was washed in running water. In some cases films were also made with Indian ink, as in Burri's method for demonstrating *Sp. pallida*. Quite early in my work I entirely gave up the use of any of the mordanted stains with aniline dyes or with silver, as used in flagella staining, as I found that

infinitely clearer and much more reliable images of all virus bodies were obtained by the slower Giemsa staining.

OBSERVATIONS

During a research, extending over more than two years, in which I have been coöperating with Dr. M. H. Gordon on various virus diseases, notably cases of lymphadenoma, I have had ample opportunity of examining microscopically numerous pathological material for virus bodies, and as controls.

Rheumatic fever.—Although rheumatic fever has been regarded as having many of the characters of an infective disease, the actual exciting cause still seems undetermined. Various cocci, diplococci, and more especially streptococci, have been suggested as the probable cause, yet none of these has received general acceptance.

Dr. Gordon sent me films made from recent exudate on the visceral layer of the pericardium of a boy of 16 who had succumbed, on April 17th, 1934, to acute rheumatic fever with pericarditis, and also a little later some capillary tubes containing a 1 in 10 suspension in broth of the inflamed pericardium. On microscopical examination of the Giemsa-stained films made directly from the pericardium I saw very small but very definite round or oval bodies, mostly isolated, a few in pairs, but rarely in chains. They were faintly stained red with Giemsa and were best seen on the stained fibrin background. They resembled all other virus bodies, not only in their difficulty in staining a faint red colour, but also in the fact that they show minute flagella-like appendages when carefully examined under a high power. Giemsa-stained films when examined by dark-ground illumination show these minute bodies very distinctly, and small as they are, they appear as very conspicuous and distinctive objects even when seen with the 8 mm. apo. objective, especially with the comp. ocular 18.

Films made from the suspension in broth, fixed and stained as above, show masses of these small bodies some singly, many in twos or threes, and not a few in short chains. Here they were often seen connected together by exceedingly delicate filaments. Films made from the suspension with Indian ink as in Burri's method show the character and shape, and especially well the filaments connecting three or four of these bodies.

The actual size of these virus-like bodies is very difficult to determine, but when measured by Nelson's extinction method they appeared to vary from about 0·17 to 0·26 μ in diameter, and measurements taken from photomicrographs give very similar figures. They are considerably smaller than the Paschen bodies of vaccinia or the Hodgkin bodies of lymphadenoma. It is well however to point out that measurements of virus bodies in general, as made by such experts as Mr. E. M. Nelson and Mr. Eliot Merlin, differ very considerably from those given by most English workers, especially when estimated by filtrative methods, and I generally find that my estimation of size is about double that given by such workers.

The accompanying photomicrograph (reproduced on Plate), taken from Giemsa-stained preparations, gives a better idea of the appearance of these very small bodies than any verbal description.

Pericardial fluid.—From June to November, 1934, Dr. Gordon kindly sent me both the fluid and films from the pericardial exudate of 50 cases dying from various causes. These patients, whose age ranged from infancy to extreme old age, had died from the most varied conditions—accidents, sepsis, malignant, leukæmia, hydrocephalus, meningitis, &c. Of these exactly half showed virus bodies closely allied to those found in the endo- and pericardium of rheumatic fever. Of course, in some other bacteria—e.g., diplococci, streptococci—were also present.

Rheumatoid arthritis.—During July and August, 1934, films and fluid from affected joints—mostly the knee-joint—were sent by the late Dr. Vincent Coates, through the kind office of Dr. Leo Delicati, from the Royal Mineral Water Hospital, Bath. These joints had, I understand, been aspirated as part of the treatment, and the notes stated that in most of these cases many joints are now affected. In 3 out of 5 of these cases I found very numerous virus bodies resembling those seen in the pericardial fluid of the case of rheumatic fever.

Dr. Douglas Collins, who had been appointed for special research work at the Royal Bath Hospital, Harrogate, kindly sent fluid from the knee-joints of 3 cases of rheumatoid arthritis. One of these fluids was unfortunately contaminated, but in one of the other two very numerous virus bodies were found. Earlier in the year fluid and films from a case at St. Bartholomew's Hospital were sent, and this proved positive. Thus out of 9 cases 5 at least were positive. In all these cases films were stained also with Ziehl-Neelsen's method, and a prolonged search was made for acid-fast bacilli, as these have been said to be often present in the joint fluid of cases of rheumatoid arthritis. In none of them did I find any evidence of tubercle or other acid-fast bacilli.

COMMENT

The questions which naturally arise are what do these small bodies—which have all the characteristics of the virus bodies found in many filtrable diseases which I have been studying for more than 20 years—represent? Are they the actual infective cause of acute rheumatic fever on the one hand, and of rheumatoid arthritis on the other; and how is the presence of somewhat similar bodies in 50 per cent. of the pericardial fluid of other conditions to be explained?

These are questions which it seems impossible at present to answer. My impressions are that probably the virus bodies found in the pericardial fluid of the case of rheumatic fever and those found in the joint fluids of rheumatoid arthritis may belong to the same species, and might well represent the actual causal organism. From a clinical and pathological aspect both these diseases are more closely associated with a virus than a bacterial origin, but I must leave the solution of these questions to those more able to answer them, and time may solve some of the problems. In this brief note I have only recorded what the microscope has revealed.

I would here like to record my sincerest thanks to Dr. M. H. Gordon, F.R.S., for his invaluable help, suggestions, and kindness in supplying me with material over such a long period.

GLOUCESTERSHIRE ROYAL INFIRMARY.—The workpeople's contributory scheme has obtained 15 new groups. A new X ray department and a new nurses' lecture room are to be added to the hospital.

WESTON-SUPER-MARE HOSPITAL.—The work of this hospital continues to expand, and last year the total number of in-patients was 1126, which constituted a record. The number of out-patients has increased from 795 to 1131 in the last two years. Ordinary income exceeded ordinary expenditure by £272. The completion of the buildings and equipment caused an expenditure of over £3000 on capital account.

PYELITIS

ITS SIGNIFICANCE AND TREATMENT*

By Arthur Ellis, M.D. Toronto, F.R.C.P. Lond.
DIRECTOR OF THE MEDICAL UNIT, LONDON HOSPITAL;
PROFESSOR OF MEDICINE, UNIVERSITY OF LONDON

(WITH ILLUSTRATIONS ON PLATE)

The subject I have chosen for my lecture has three attractions: first, it is one of the few conditions common both in the wards of a hospital and in general practice; secondly, it is one which is amenable to treatment; and thirdly, there have lately been advances in our knowledge of it which may not yet be generally familiar.

Pyelitis is common; its symptomatology is well known and the diagnosis usually easy. Accordingly I do not propose to say anything here about symptoms and about diagnosis, only to recall that when the condition occurs in infants it is readily missed; hence it should always be remembered as a cause of pyrexia of unknown origin in these patients. The general public commonly speak of pyelitis as "cystitis"; but primary cystitis is in fact relatively rare, and the great majority of cases of so-called cystitis are in women examples of pyelitis, in men of prostatitis. Acute cystitis, when it does occur, is usually accompanied by a degree of strangury greater than that seen in acute pyelitis and usually also by tenderness over the bladder, a sign which is absent in pyelitis.

THE SIGNIFICANCE OF PYELITIS.

An appreciation of the anatomy and physiology of the pelvis of the kidney and ureter is essential to an understanding of the significance of pyelitis. The renal pelvis and ureter are not, as we used to consider them, merely passive structures conducting the urine secreted by the kidney to the bladder, but are active structures with muscular walls, which, by their contraction, pass the urine along its appointed course. We now know that both pelvis and ureter have a slow peristaltic activity. We believe also that there is a sphincter-like action at the point of junction of pelvis and ureter and also at the opening of ureter into bladder. The accompanying intravenous pyelograms show well the difference in size of the pelvis in systole and in diastole (Fig. I. on Plate).

The importance of this conception of the active flow of urine in the pelvis and ureters lies in the fact that only when interference with the outflow of urine is present is infection of the pelvis of the kidney likely to occur. The importance of proper emptying in the prophylaxis of bladder infections is generally recognised. A normally emptying bladder is infected with difficulty and, if infected, usually rapidly recovers; whereas in the bladder with retained urine even the most careful catheterisation leads to infection and this infection is difficult to overcome until adequate drainage is established. It is perhaps not so generally appreciated that the same rule holds for the pelvis of the kidney. The normally acting pelvis, ureters, and bladder are rarely infected and clear rapidly if they are, whereas anything which leads to a retention of urine within them renders them at once susceptible to infection and makes such infection difficult to overcome.

This brings us to the causes of obstruction of urine within the renal pelvis. This method of approach is valuable, because it gives us a rational understanding of the causes of pyelitis and should *lead* to the examination of our patients with pyelitis for such obstruction. No case of pyelitis should be considered satisfactorily explained until some cause of urinary obstruction within the bladder, ureter, or pelvis has been demonstrated.

Pregnancy easily occupies first place as the commonest cause of obstruction to normal urinary flow; it is not surprising therefore that it is also the commonest cause of acute pyelitis. From the results of intravenous pyelography we have learnt that dilatation of one or both ureters, most frequently the right, is so constant in pregnancy that it may almost be described as normal. The degree of dilatation is well demonstrated in Fig. II., which is a pyelogram taken at the fifth month of an uncomplicated first pregnancy. The explanation of this dilatation is still quite uncertain; it is not known whether it is due to direct pressure of the gravid uterus on the ureter or to paralysis of the nerves supplying it, or to some quite other mechanism. The dilatation begins quite early in pregnancy, persists until after parturition, and then rapidly subsides; as a rule the ureter and pelvis seem to regain their normal appearance about three weeks after delivery. There is some evidence that the occurrence of infection may retard this return to normal and that in some cases of chronic pyelitis the ureters and pelvis remain permanently somewhat dilated.

The other causes of urinary retention in the pelvis and ureters, and an accompanying pyelitis, are much less common and important. Calculus, which probably also acts by locally lowering the resistance; malformation of the urinary tract, such as double pelvis, double ureter, and displaced pelvic-ureteric openings; aberrant renal arteries constricting the ureter; tumours of the kidney or pelvis or of [illegible] structures pressing on the ureter; inflammation [illegible] within the kidney, such as renal tuberculosis, [illegible] outside it, involving the ureters—e.g., with [illegible] and neuromuscular defects leading to [illegible] opening of the sphincteric orifices—[illegible] causes which are met with, and [illegible] looked for, in cases of pyelitis not [illegible] explained. The frequency of [illegible] of the ureters and renal pelvis [illegible] bladder due to prostatic enlargement [illegible] of the spinal cord needs no [illegible] of the bladder symptoms [illegible] attention to the [illegible] former group of cases [illegible] ureter and pelvis only [illegible] lying lesion is apt to [illegible] of the pyelitis is [illegible]

The following cases [illegible] thorough investigation [illegible] pyelitis:—

Case 1.—[illegible] under treatment [illegible] had various [illegible] vaccines. [illegible] and [illegible] in the [illegible] [illegible] three months pregnant, this being her first pregnancy. For two months she had had increasing frequency of micturition. On examination there was tenderness in the region of the right kidney. The urine contained pus and *Bacillus coli* and radiography showed a group of shadows in the right renal region (Fig. IV.). Cystoscopy (indigo-carmine): left, 6 minutes; right, no colour after 10 minutes. Both ureters catheterised: left, normal urine; right, pus and *B. coli*. This patient had never any urinary symptoms before her pregnancy. Two months after delivery Mr. Dix performed a nephrectomy; a grossly damaged kidney with multiple calculi was removed.

---

* A post-graduate lecture at the London Hospital.

CASE 3.—E. F., a female aged 43, was admitted to the London Hospital with pain in the back and frequency. Two weeks before admission she had had a sudden onset of pain in the small of the back, with shivering and headache; there was burning pain on micturition and frequency. The symptoms lessened after three days and she had felt better until the day before admission when she had a similar attack; her doctor had found albuminuria. Fourteen years ago she had influenza followed by "fluid in the chest," she was in Victoria Park Hospital at that time. The patient is married and has one child; she had no urinary disturbance during the pregnancy. Examination showed a furred tongue, fever, and pyuria; it was otherwise negative.

The symptoms cleared rapidly with treatment. A routine intravenous pyelogram showed a conspicuous dilatation at the lower end of the right ureter (Fig. V.). On cystoscopic examination this proved to be a large ureterocele.

CASE 4.—G. H., a girl aged 18, had been under observation since 1927 with recurrent attacks of "pyelitis," in which there was pain in the back, some frequency, and puffiness of the face and ankles in the morning. The urine consistently contained either pus, or numerous leucocytes, and grew *Bacillus coli* on culture. X ray and cystoscopic examination had been carried out in 1931 with negative results. Uroselectan pyelography revealed definite left hydronephrosis and some dilatation, but no deformity of the right pelvis (Fig. VI.). Operation revealed bilateral streptococcal salpingitis, with abscess formation on the left side and an inflammatory mass incorporating the left Fallopian tube and ovary, fixed to the iliac vessels and pelvic wall, and obstructing the left ureter. The whole mass was removed between ligatures.

Above I have described conditions within the urinary tract predisposing to its infection; but it should be remembered that the foci of infection in other parts of the body, such as the appendix and the gall-bladder, may also play a part. This is often emphasised by those writing on pyelitis. In my own experience I have not been impressed with its importance, but it is perhaps not without significance that among the relatively few patients whom I have treated with a ketogenic diet two have shown symptoms suggesting exacerbation of chronic gall-bladder infection.

TREATMENT

The treatment of pyelitis may be conveniently divided into the treatment of the acute condition with relief of symptoms and the treatment of chronic cases and the eradication of the infection. The former is one of the most satisfactory therapeutic procedures we have; the latter unfortunately gives much less good results.

The treatment of the acute condition is extraordinarily simple; it consists in the administration of adequate doses of alkali over a sufficiently prolonged period. The important words in the above sentence are the qualifying ones—"adequate" and "sufficiently prolonged." Over and over again one is asked to see cases of acute pyelitis which are not responding adequately to treatment; almost always this result is due simply to failure to give the drug in sufficient doses for a long enough time. In using alkalis it is the common practice to use a mixture of alkaline salts. This is, I think, a mistake. It is my experience that a single salt is less likely to cause nausea and vomiting than a mixture. I use potassium citrate, grs. 60 in ½ ounce of water with syrup of orange or lemon to flavour. Half an ounce of the above mixture—that is, pot. cit. grs. 60—is given 2-hourly for eight doses and then 4-hourly. If after 36 hours of such treatment the urine is still acid, 2-hourly doses should again be given. When all symptoms have disappeared the alkali may be reduced to three doses in 24 hours, provided this is adequate to maintain the urine alkaline to litmus. A very common error is to discontinue the alkali too early or to substitute for it acid sodium phosphate and hexamine The administration of alkali should be continued for weeks and should be *maintained after the patient is up and about.* If nausea or vomiting are induced by the citrate, potassium or sodium acetate, which are equally effective, should be tried: some patients can take the one and not the other. I have personally entirely discarded the use of hexamine in these cases.

With adequate treatment with alkalis the symptoms usually disappear rapidly; the pain goes, the temperature returns to normal, and the pus in the urine diminishes. Occasionally these measures are unsuccessful, and in spite of adequate alkali therapy the pain persists, the temperature remains elevated, and further rigors occur. Such patients are usually very ill and their condition may give rise to anxiety.

Recently, with the assistance of Mr. Dix, I have obtained very successful results in such circumstances by continuous drainage of the renal pelvis through a ureteric catheter. The ureter is catheterised and the catheter passed into the pelvis of the kidney and left in situ for 48–72 hours. The change in the patient is dramatic; the pain is instantly relieved, the temperature quickly falls, and the restlessness and toxic manifestations disappear. We have now treated three patients in this way with uniformly successful results. In the two instances in which we examined the urine obtained from the kidney pelvis by catheterisation we found it acid to litmus, although the bladder urine was, and had been on the previous day, alkaline. Moreover, indigo-carmine injected in one case seven, in the other eight, minutes before the catheterisation had not yet appeared. This suggests that in these patients swelling, or other interference with the pelvic-ureteric opening had occurred, with retention of urine and a resulting rise in pressure within the pelvis of the kidney sufficient to prevent the secretion of urine by that kidney. This failure of the kidney to secrete, and the resulting acidity of the urine is sufficient explanation of the failure of alkalis to relieve symptoms. The immediate relief of pain which follows the introduction of the catheter suggests that the severe pain in these patients is due to the increased pressure within the pelvis. It has been very noticeable that, in each instance after pelvic catheterisation, a prolonged and continuous rapid flow of urine greatly exceeding the normal has resulted. I feel that pelvic drainage by ureteric catheter is a very important addition to our treatment of acute pyelitis; its use will, I believe, result in a disappearance of the case refractory to alkali therapy.

The treatment of chronic pyelitis and the elimination of the infection after an acute attack may be considered together. Unfortunately our methods of treatment are here much less satisfactory. Acute attacks of *B. coli* pyelitis in children usually show complete recovery without relapse and with elimination of the infection. In acute pyelitis of pregnancy, by far the commonest form in the adult, chronic pyelitis, relapsing acute ttacks, and basal cystitis with persistence of *B. coli* in he urine are, on the other hand, so frequent as to be lmost the rule. It is probable that this persistence of nfection is dependent on inadequate emptying of the pelvis and ureters, due either to mechanical defects or to disturbance in the emptying mechanism due to the chronic inflammation. As yet our methods are inadequate to demonstrate such an effect in most cases, but the frequency of the association of infection with anatomical abnormalities and the relative rarity of infection of the normal pelvis make tenable such an hypothesis.

In the treatment of chronic pyelitis a ketogenic diet has been advocated. On such a diet very rich in fat and very low in carbohydrate, ketone substances are excreted in the urine. These ketones are bactericidal, especially in a highly acid urine. It is usual therefore to give, along with the diet, acid-producing salts such as ammonium chloride or ammonium nitrate in relatively large doses. My own experience with this form of treatment is insufficient to dogmatize. There is no doubt that it often does lead to elimination of the infection—in about half the cases in the experience of most authors. My own experience suggests that the treatment is difficult to carry out without the assistance of a trained dietitian. Even with the assistance of a dietitian I have found it quite inapplicable to out-patient treatment. The diet is trying to most patients and some find it impossible. In two instances I have seen symptoms suggesting an exacerbation of a dormant cholecystitis in patients on the high fat diet. It is probable that when efficiently carried out its success or failure depends on the adequacy of pelvic emptying in the particular case.

Other urinary antiseptics, such as hexamine, neotropine, and hexyl resorcinol, are often employed. I have not had much success with them. Vaccines I have not used and I know of no satisfactory evidence of their efficiency.

Renal lavage with colloidal silver undoubtedly relieves pain in some patients with chronic pyelitis. Occasionally the urinary findings also improve and pus and bacteria may disappear from the urine. It is questionable whether the benefits obtained are due to the substance injected. Not infrequently such patients are equally relieved by the passage of a ureteral catheter or the making of a pyelogram. It may well be that the improvement following renal lavage is due merely to improved drainage resulting from the pelvic catheterisation. Renal lavage should, in my opinion, be done only by the expert. In unskilled hands considerable discomfort and actual damage may result from its use.

The most common sequel of acute and chronic pyelitis is basal cystitis, in which a chronic inflammation with multiple cyst formation is present about the trigone and neck of the bladder. It is this condition which is most often responsible for the persistence, or recurrence, of painful and frequent micturition in patients who have previously had pyelitis. Treatment with alkalis will often give symptomatic relief in this condition, but is also often ineffective. In such patients symptomatic relief is usually obtained by careful local treatment with caustics or cautery. This, like renal lavage, is a treatment to be employed only by those well versed in the technique of cystoscopy, unskilled interference not infrequently resulting in exacerbation of the existing condition.

In conclusion may I again plead for a careful and thorough investigation of all cases of unexplained pyelitis; and for an adequate use of alkalis in the treatment of the acute condition.

A DIRECTOR FOR THE INSERTION OF THE SMITH-PETERSEN NAIL

IN COLLUM FEMORIS FRACTURES

By Eric I. Lloyd, M.B. Camb., F.R.C.S. Eng.

ORTHOPÆDIC SURGEON TO THE ROYAL NORTHERN HOSPITAL, LONDON; SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET; CONSULTING ORTHOPÆDIST TO THE LONDON COUNTY COUNCIL

This new instrument enables the surgeon to insert a Smith-Petersen nail through a small incision over the great trochanter without the use of wires and without exposure of the fractured neck of the femur. It is an instrument of precision and its setting in each case is determined by X ray photography in two planes of a part of the apparatus (the guide nail) which is first driven into the great trochanter.

This nail relates the apparatus to the bone and becomes temporarily a part of it. Direct measurements are made on the X ray film and subsequently transferred to the apparatus, which is not fixed to the operating table, and is consequently independent of horizon, spirit levels, degrees of internal rotation, or anteversion. The instrument was first made to take Kirschner wires, but it has now been improved so that wires are entirely eliminated from the whole operation.

The guide nail is used as a means of obtaining an exact setting of the instrument for inserting a Smith-Petersen triradiate nail in any direction which the operator desires. It allows sufficiently fine adjustment to aim the nail exactly where it is wanted.

The apparatus, which can be used for either lower limb, is made of stainless steel and consists of a rectangular guide nail 16·0 by 1·0 by 0·5 cm., with a reduced fluted end. A Duralumin tube is connected to this by two sliding arms at right angles to one another and graduated in centimetres. This tube is of such a size that a Smith-Petersen triradiate nail will slide down it and continue on a set course into the bone. In addition to the linear adjustments there are two quadrants marked in degrees whereby the angle of the duralumin tube can be varied in two planes at right angles to one another.

The guide nail is perforated at intervals of 1·0 cm. in two planes; these perforations are visible on the radiograms and provide a standard unit of measurement nearly independent of X ray distortion.

The X ray apparatus should be "shock-proof" and ether anæsthesia avoided. It is probably also a wise precaution to "earth" both the operating table and the X ray apparatus.

Insertion of the guide nail.—The fracture is reduced on an extension table and held fast in the abducted and internally rotated position. The guide nail is then hammered through a stab incision into the surface of the great trochanter at a point about 2·0 cm. below its tip (i.e., towards the feet) and near the middle of its lateral surface. The nail should penetrate the bone far enough to get a firm grip and so avoid all risk of subsequent wobble or rotation. A dip-stick rod is passed alongside the nail to the surface of the bone to measure bone penetration which should be approximately 2·5 cm. In the usual operative position of the limb for reduction of these fractures the nail must be directed approximately at right angles to the general line of the trunk and must be so held that two of its four surfaces look directly up and down — i.e., towards the ceiling and floor of the operating room.

Radiograms are now taken in two planes at right angles to one another, and if reduction of the fracture is satisfactory the appropriate setting for the instrument is worked out as follows.

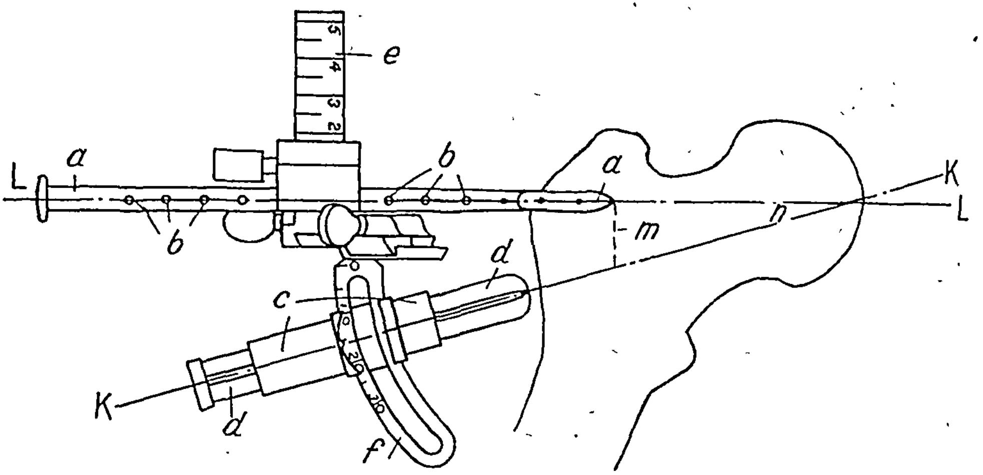

FIG. 1.—Scheme of antero-posterior radiogram with director and Smith-Petersen nail in position. (*a–a*) Guide nail. (*b*) Perforations 1 cm. apart. (*c*) Duralumin tube which sets the course of the Smith-Petersen nail. The setting of the tube is controlled by the four adjustments (*e*), (*f*), (*g*), and (*h*) (see Fig. 2). (*d*) Smith-Petersen triradiate nail in duralumin tube. (*e*) *One-way linear adjustment marked in centimetres.* (*f*) *One-way quadrant marked in degrees from 5°.* (*K–K*) Selected line for Smith-Petersen nail. (*L–L*) Projection of line of guide nail. (*m*) Perpendicular from end of guide nail to selected line for Smith-Petersen nail. (*n*) Angle between selected line for Smith-Petersen nail and projection of guide nail.

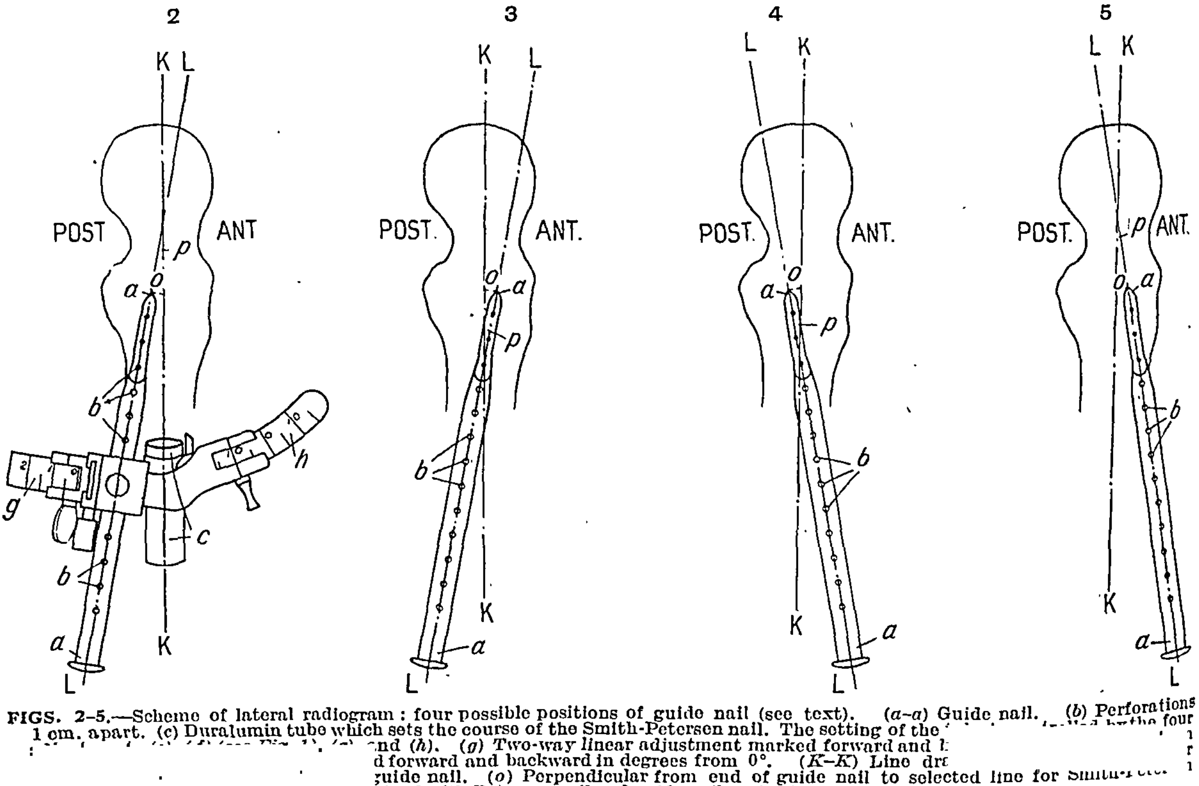
Calculating the setting of the instrument.—The surgeon has before him two wet films showing the fracture satisfactorily reduced and showing also the guide nail penetrating the great trochanter. The first of these films (Fig. 1) is the ordinary antero-posterior and the second (Figs. 2, 3, 4, 5) is a lateral of the neck of the femur which is really an infero-internal–supero-external view.

The antero-posterior film is held to the light and a straight line (Fig. 1, *K–K*) is drawn upon it where the operator wishes to place the triradiate nail. The guide nail is then projected on the X ray film (Fig. 1, *L–L*) until it meets this, and a line (*Fig. 1, m*) is drawn at right angles to the guide nail from its point to meet the line (Fig. 1, *K–K*) selected for the Smith-Petersen nail. The length of this perpendicular in centimetres is obtained by comparison with the photographed perforations in the guide nail which are known to be 1 cm. apart. This figure gives the downward (towards the feet) adjustment necessary on the linear scale (*e*). In order to obtain the correct setting for the quadrant (*f*) it is only necessary to measure the angle (Fig. 1, *n*) between these two lines *L–L* and *K–K*.

The lateral X ray film (Fig. 2) is then examined and the same two measurements obtained—viz., correct settings for the linear scale (*g*) in centimetres and for the quadrant (*h*) in degrees.

There is a difference between the two sets of



FIGS. 2–5.—Scheme of lateral radiogram : four possible positions of guide nail (see text). (*a–a*) Guide nail. (*b*) Perforations 1 cm. apart. (*c*) Duralumin tube which sets the course of the Smith-Petersen nail. The setting of the [illegible] four [illegible] and (*h*). (*g*) *Two-way linear adjustment marked forward and* [illegible] d forward and backward in degrees from 0°. (*K–K*) Line dr[illegible] guide nail. (*o*) Perpendicular from end of guide nail to selected line for Smith-Peter[illegible] for Smith-Petersen nail and guide nail projection.

readings inasmuch as the first two adjustments can only be made in one direction, and the second pair can each be made in one of two directions. This is because an essential step in the introduction of the guide nail is to insert it into the trochanter above the point at which the Smith-Petersen nail is to enter and in such a way that it makes an acute angle with the line of the neck of the femur. This is perfectly simple if the instructions already given under "insertion of the guide nail" are followed. To put the matter in another way, the two adjustments obtained from the lateral X ray photograph can be made on either side of the zero mark, but the apparatus is so constructed that zero in the coronal plane is at one end of the scale and adjustments are only possible in one direction, beginning at 1 cm., on the linear scale (*e*) and 5° on the quadrant (*f*).

It is therefore important to mark the lateral X ray photograph in order to avoid any possibility of confusion between the anterior and posterior surfaces of the femur.

Fig. 1 illustrates the setting of the instrument obtained from the antero-posterior X ray photograph—e.g., 1·8 cm. (Fig. 1, *m*) 16° (Fig. 1, *n*).

Figs. 2, 3, 4, and 5 show four possible positions in the lateral X ray photograph. The readings in each of these examples should be as follows:—

From Fig. 2 ..	0·5 cm. forward (0);	10° forward (p.).
From Fig. 3 ..	0·5 cm. backward (0);	10° forward (p.).
From Fig. 4 ..	0·5 cm. forward (0);	10° backward (p.).
From Fig. 5 ..	0·5 cm. backward (0);	10° backward (p.).

These adjustments are made on the instrument as it is slid into position on the guide nail.

Choosing the nail.—It is important to use a nail of the right length. My set at present consists of seven nails varying in length from 10 cm. to 7 cm., with 0·5 cm. difference between each consecutive pair. The length is that of the nail, excluding the head, since that does not enter the bone. The length of each nail is engraved on the outer side of the head.

The line drawn on the antero-posterior radiogram to represent the path of the triradiate nail is now measured in terms of the photographed perforations on the guide nail and the correct length of nail thus ascertained. The selected nail should as a general rule be a little shorter than the calculated length, otherwise it may partly emerge from the hemispherical head of the femur which is only shown in outline on the X ray film. In subcapital fractures it may be necessary to deduct for operative impaction and to add for nail obliquity, but in the transcervical group this is probably unnecessary because the greater size of the proximal fragment gives a greater margin of safety.

The nail starter.—A special nail starter is used to start a track for the Smith-Petersen nail which might otherwise be deflected from the correct course by one of its three fins encountering bone before the other two. A 3 cm. incision is now made in the long axis of the limb through the correctly adjusted duralumin tube; the starter is passed through the tube and tapped into the bone for about 4 mm and then removed.

The insertion of the nail.—The selected nail is then passed down the duralumin tube and tapped into the bone with a hammer and punch. When it is estimated to have entered the bone for about 3 cm. fresh antero-posterior and lateral radiograms are taken to check the procedure and the nail is then hammered home. The apparatus is now removed, the extension released, and the fracture impacted by a few heavy blows on the great trochanter with an impactor of Smith-Petersen's type. Final X ray photographs are taken and the wound is then closed in two layers (generally without drainage) and dressings applied.

NOTE

Certain relevant matters have been purposely omitted from this paper which it is hoped to supplement later. Amongst these important points are the following: (1) Results obtained by the method. (2) Choice of anæsthetic. (3) X ray technique. (4) Experience with a large nail instead of the usual 13 mm. diameter. The accuracy of the director makes this quite feasible but the large nail has been used on one occasion only. The standard size of Smith-Petersen triradiate nail has been used in all the other operations.

The brotherhood of medicine knows no boundaries, and I gladly own my debt to the writings of Smith-Petersen of Boston, Böhler of Vienna, King of Melbourne, Brocq and Dulot of Paris, and Burns of London, but above all to Sven Johansson of Gothenburg, whose admirable work on "Collum Femoris Fractures" has set a new standard of achievement in these difficult cases.

This instrument has been made to my requirements by the Medical Supply Association of 167, Gray's Inn-road, London, W.C.1, and I wish to acknowledge the help of the managing director, Dr. G. E. Greville, and his assistant, Mr. F. C. Hickman, as well as that of the radiographic staff of more than one hospital.

Clinical and Laboratory Notes

AN UNUSUAL INFECTION OF THE ANTRUM, OF DENTAL ORIGIN

By E. C. N. Strong, F.R.C.S. Eng., L.D.S.
EAR AND THROAT SURGEON, BIRMINGHAM MUNICIPAL HOSPITALS; AND

I. B. Barclay, M.R.C.S. Eng., D.M.R.E., D.P.H.
RADIOLOGIST, SELLY OAK HOSPITAL, BIRMINGHAM

(WITH ILLUSTRATIONS ON PLATE)

A boy, aged 15, was admitted to the Selly Oak Hospital on March 5th, 1935, with symptoms of nasal sinusitis over a period of twelve months. They were said to have started soon after an attack of toothache in the left central upper tooth.

On admission he had pus in the middle meatus of his nose of the left side, the right being practically clear. On transillumination the left antrum was dim; radiographic investigation (Fig. I. on Plate) showed definite abnormality in this antrum. It was decided, on account of posterior nasal discharge, to wash out his sinuses by the Watson-Williams method. This was done, with the result that mucus only was found in both ethmoids; the right antrum was clean and the left contained pus, which on culture grew streptococci. There was no indication in his nose of any other pathological condition, except that localised in his left antrum. Five days after this was done he complained of pain in the left side of his face, which was slightly swollen. Nasal examination was negative, but he had a tender left upper central, which contained a temporary filling, said to have been put in six months previously. This tooth was painful and was loose; it was therefore decided to extract this, as the condition was a dental one. On examination of the tooth it was found that the root-filling material had passed through the apex into the alveolus, and was surrounded by an area of granulation tissue (Fig. II.). Radiological evidence indicated that the tooth pulp had been removed, and that a radio-opaque substance had been put in as a root-filling, clearly passing through the apex. In view of this latter condition, an occlusal film was taken (Fig. III.), which showed an area of rarefied bone spreading up into the floor of the antrum of the same side. After this tooth had been extracted the condition subsided, and subsequent lavage of the antrum proved clear. The patient left hospital on March 26th with no further symptoms.

This case is put forward for two reasons: firstly, it is suggested that the condition was an antral suppuration of dental origin, arising from a central incisor (an unusual occurrence); secondly, that undoubtedly the apex of this tooth was septic and was root-filled. Whether the root-filling had, in passing through the apex, spread the infection, or whether there was a pre-existing antral infection before the dental treatment, is open to doubt, but events after treatment show that the two were correlated, and it was, in fact, a direct extension from the tooth socket to the antrum floor. The fact that the ethmoidal cells of the same side were devoid of any pathological condition also suggests that the antrum infection was of dental origin. Normally, it is very common to find an ethmoiditis and an antritis, the usual sequelæ of a primary nasal pansinusitis.

The floor of the maxillary sinus is formed by the alveolar process of the maxilla, the thickness of the floor depending upon the degree of hollowing-out of this process. Where this hollowing-out is very pronounced, the floor must bear an important relation to some of the teeth and their sockets, and may even contain irregular elevations corresponding to the roots of the teeth. Such relationship depends upon the thickness of the layer of spongy bone, which varies much in different skulls, and even on the two sides of the same skull. Bony septa, varying in height and thickness and dividing the floor into pockets, often traverse the floor of the sinus; since the maxillary sinus varies greatly in size, and even on the two sides of the same skull, it is obvious that the relation of the teeth to the sinus can never be exactly constant. When the layer of spongy bone along the floor of the sinus is thin—i.e., when the maxilla is markedly hollowed out—the floor is at a lower level than the floor of the nose; if the alveolar process is comparatively thick, the floor of the nose is at a lower level than the floor of the sinus. Resschreiter states that it is a male characteristic for the sinus floor to be inferior to the nasal floor, but other observers have been unable to verify this observation.

In general terms the maxillary sinus varies greatly in size, shape, and positions, not only in different individuals, but in each side of the same individual; it does not attain its maximum size until the third decade of life, and thereafter appears to remain stationary. The base of the sinus is extremely variable, and no definite information as to its constant size and shape can be given. It is therefore obvious that when a radiographic study of the canine and bicuspid teeth has to be made, with reference to the maxillary sinus, it is essential that the floor of the sinus should be clearly delineated. Our experience has been that this can only be satisfactorily carried out with the patient in the upright position. Frequently stereoscopic examination is extremely helpful.

The teeth most often involved in antral sepsis are the molars and bicuspids, but it is possible that the canine and also, as is shown, the central, can be the cause of sepsis in this sinus; this is almost entirely due to the anatomical configuration of its outer and front wall. In this case the inflammatory condition is liable to spread towards the ascending process of the superior maxilla, rather than to run along the cancellous tissue of the antral floor.

We are indebted to Dr. S. Robinson, pathologist to Selly Oak Hospital, for her investigation of the bacteriology of this case.

FATAL POISONING CAUSED BY MORPHINE IN A PROPRIETARY REMEDY

By Arnold Renshaw, M.D. Lond., D.P.H.

DIRECTOR OF THE LABORATORY OF APPLIED PATHOLOGY AND PREVENTIVE MEDICINE, AND HON. PATHOLOGIST TO ANCOATS HOSPITAL, MANCHESTER

I HAVE never heard of an infant succumbing to a dose of morphine so small as that given in the following case.

The weight at birth was 6¼ lb. On Oct. 30th, 1934, when the child was eleven days old, the mother, in view of supposed constipation, gave it in the milk feed a few drops of a proprietary remedy called Cherub's Balm. On Nov. 1st, at 3 A.M., a further dose of one teaspoonful was given, after which the child cried for a time and then slept. It was still asleep when the family practitioner (Dr. H. Tomlinson) called in the morning, but the mother did not mention that medicine had been given. At 6 P.M. the mother asked the doctor to call again, but the child died at 8 o'clock without regaining consciousness.

Autopsy.—I carried out a post-mortem examination. The body showed lividity of the ears and the nails of fingers and toes, but no signs of violence. The pupils were not contracted but not fully dilated, measuring 4 mm. in diameter. Tardieu spots were found on the surface of the left ventricle at the junction of interventricular septum, with small ecchymoses (2–3 mm. in diameter on arch of aorta), fullness of the right auricle, and congestion of both lungs, with mucus in the trachea. The small intestine was congested for about 6 feet from the pylorus, and the thymus was large though not too large for the age of the infant. The meninges were intensely congested, particularly over the vault; the spinal canal and other organs appeared normal. About 2 c.cm. of urine was withdrawn from the bladder with a syringe and submitted to analysis, together with the stomach, stomach contents, duodenum with contents, small and large intestines with contents, liver, kidneys. I also sent for examination the spoon used to measure the dose administered, the bottle containing the rest of the Cherub's Balm, and three articles of clothing, and suggested that morphine be specially sought for. These analyses were carried out by Mr. G. D. Elsdon, Lancashire county analyst.

Histological examination.—Section of the lung shows congestion of blood-vessels and in places desquamation of the alveolar epithelium. There is no evidence of pneumonia or broncho-pneumonia to account for death, and there is no pleurisy. Section through one of the areas of discoloration in the heart shows a small extravasation of blood amongst the muscle-fibres, constituting the so-called Tardieu spot, met with in asphyxia. The muscle-fibres seem normal otherwise, though the strands of muscle are somewhat widely separated from each other. The meninges of the brain are congested but there is no evidence of pus-formation in the brain or on the meninges. The thymus is also congested, but otherwise normal. These findings would accord with death from asphyxia.

Chemical analysis.—The amount of Cherub's Balm in the bottle was 33 c.cm. (1 fluid ounce = 28·4 c.cm.) and the liquid has been found to contain 0·006 per cent. of anhydrous morphine. When full the bottle would contain about 43 c.cm., so that an amount not exceeding 10 c.cm. may have been removed. The volume of the spoon supplied is 2·5 c.cm. The quantity of anhydrous morphine in the liquid remaining in the bottle was 2 mg. (1 mg. = gr. 1/65). The amount in the bottle when full would be 2·6 mg., and the amount in one dose of the teaspoon used would be 0·15 mg. The stomach, stomach contents, and duodenum proved to be free from morphine. The kidneys and urine contained not more than 0·02 mg., and the liver about the same quantity; in the intestines and their contents there was about 0·1 mg. From these findings it was concluded that more than 0·15 mg. of morphine was administered, but that some of this had passed into the blood stream.

Cause of death.—At the inquest I gave my opinion that death was due to asphyxia not caused by mechanical violence, but by morphine poisoning. A verdict of death by misadventure was returned.

Cases have been reported in which quantities of the order 0·5 mg. morphine have resulted in the death of very young children. Thus E. Smith[1] describes a case in which opium gr. 1/20 (= 3·3 mg. opium=0·33 mg. morphine) caused the death of an infant 16 days old. A. and M. Winter Blyth[2] state that cases are recorded of infants dying from extremely small doses of opium—e.g., 0·7, 4·3, and 8·1 mg. (1/90, 1/15, and ⅛ of a grain)—but in such instances one cannot help suspecting some mistake. It may be conceded, they add, that a very small quantity might be fatal to infants, and that 3 mg. (0·3 mg. of morphine) given to a child under one year would probably produce serious symptoms.

In the present case it is to be noted that although the bottle when full would contain 2·6 mg. of anhydrous morphine, only 2 mg. was found left in the bottle. The dose however was given by candlelight, and the mother in evidence stated that she had knocked over the bottle and that some had escaped in this way. It can be assumed therefore that at least 0·15 mg. was administered but possibly less than 0·3 mg., of which 0·14 mg. was recovered from the stomach, duodenum, large and small intestines, liver, kidneys, and urine. In evidence at the inquest the manufacturer stated that he thought the medicine was safe and that he had heard of children drinking out of the bottle; he further stated that the morphine content was not ascertained by analysis. Accepting 0·5 mg. as a known lethal dose and 0·3 mg. or less as the dose given in this case, the bottle would contain 5–8 times the known minimum lethal dose. In view of the known idiosyncrasy of young children to morphine and the variable composition of syrup of poppies used in the medicine I offer the following suggestions.

1. All such preparations should be analysed for morphine content and a log book kept of all batches made and sold.
2. All such preparations should be sold only under Schedule 1 of the Poisons and Pharmacy Act, 1908, and the same description should be applied as is at present applicable under the Ireland Schedule (Part II.). Thus the present schedule exempts any preparation containing less than 0·2 per cent. morphine from Part I. of the schedule, whereas Part II. of the Ireland Schedule includes "Opium and all preparation of opium or poppies." Since the present medicine which contained only 0·006 per cent. morphine was able to cause death it is obviously possible for an unscrupulous person to encompass the death of an infant by the free use of preparations containing much less than the specified amount of morphine without any register of the sale of such a product being available.
3. The inspection of premises and records of all such manufactured products should be made possible by amending the Dangerous Drugs Acts, 1920, 1923, 1925, in such a way as to alter the amount of morphine from 0·2 per cent. to much less in amount before premises come within the purview of these Acts.

I am aware that this case may be an isolated one; on the other hand, others may not have been recognised, through suppression of information.

I wish to thank Mr. R. M. Barlow, the coroner, for permission to report these facts, and Mr. G. D. Elsdon for allowing me to give his chemical results.

A CASE OF LEOPARD BITE

WITH A NOTE ON CLAW MARKS

By James Walker, M.B. Glasg., D.P.H.
MEDICAL OFFICER, BEBIANIHA, GOLD COAST

On Jan. 7th, 1935, a Sefwi hunter was brought to the African hospital belonging to Bibiani (1927) Ltd. suffering from injuries inflicted by a leopard. Either by accident or bad shooting, he had hit the creature near the tail, so angering it that it turned on him and pulled him down, worrying him till two other hunters killed it. His left arm just above the wrist was bitten through, both bones being crushed. Both his arms were clawed extensively, and a fang had passed right through the inner side of the right orbital fossa to the floor of the skull, missing the eyeball. An unusual feature of the case was that a bite in the throat had pierced the trachea in such a manner as to leave a valve which caused air to be pumped into the tissues of the neck and face, producing conspicuous surgical emphysema. The patient was conscious, and his breathing obstructed and difficult; so I opened up the wound so far as was necessary to allow of easy respirations, and for some three hours he was comfortable. Then he announced he was going to die and did so.

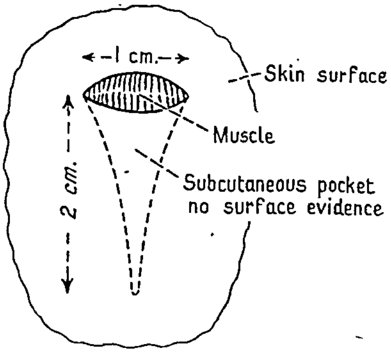


Diagram showing the gaping wound in the skin (through which muscle is visible), and the long subcutaneous pocket, not at first evident, made by the leopard's curved claw.

The accompanying diagram shows a type of claw mark seen on the right arm. These lesions were roughly half-moon-shaped and looked deceptively clean-cut and shallow, but in addition to the obvious wound there were conical pockets running well under what looked like sound skin, following the curves of the animal's claws. This multiple pocketing, if overlooked, would give every chance to the tetanus bacillus and other bacteria. It is caused by the animal *holding* the limb, without tearing it, and differs from the rending wounds.

The late Mr. H. Johnson.—The death of Mr. Harry Johnson, house governor and secretary of the Leicester Royal Infirmary on July 14th, is announced. Mr. Johnson had held this position for 31 years, and during his long service for the hospital had seen it expand from an institution with 226 beds to one with 486 beds and 92 convalescent beds. He was a member of the British Hospitals Association, and took an active part in the deliberations of the East Midland Regional branch.

MEDICAL SOCIETIES

BRITISH SOCIAL HYGIENE COUNCIL

IMPERIAL CONGRESS

THE seventh Imperial Social Hygiene Congress was held at the London School of Hygiene and Tropical Medicine from July 8th to 12th, under the presidency of Sir BASIL BLACKETT.

The subject of the first discussion was recent efforts of the League of Nations in the fight against traffic in women. Mr. E. E. EKSTRAND opened the meeting with a paper reviewing the work of the League, which had, he said, definitely coördinated the efforts of the different countries. The League Council had come to the conclusion that the abolition of licensed houses was an essential step, but that it must be accompanied by careful measures of rehabilitation.

A number of speakers from various parts of the world contributed papers to another session on the welfare of the mercantile marine and social conditions in ports. Pre- and post-marriage problems and the best methods of teaching biology and hygiene were also discussed.

The two medical sessions dealt with the treatment of venereal disease at the present day, and with the relationship between yaws and syphilis.

Treatment of Venereal Disease

At the first of these discussions the chair was taken by Sir FARQUHAR BUZZARD and the opening paper was read by Col. L. W. HARRISON, who dealt with the recent advances in treatment and also the working of venereal disease schemes in England and Wales. Judging by the annual returns from the treatment centres, he said, no impression had been made on the incidence of gonorrhœa. On the other hand, it had never been believed that these figures really represented the number of cases in the general population; they reflected the popularity of the centres and the public appreciation of the seriousness of the disease. Far too few women were seen in the centres. More use, he thought, might be made of blood tests; the complement-fixation test for gonorrhœa had been made wonderfully sensitive and specific. A routine blood test would bring to light many cases not otherwise revealed. The most important advance in treatment had been the production of hyperpyrexia, the gonococcus being very sensitive to temperatures which could be tolerated by human tissues. Diathermy had provided a method of producing controlled temperatures which could be stopped at once if the patient were having too much. The usual routine was to enclose the patient's body in a Kettering hypertherm, through which conditioned air was pumped so that the temperature was kept between 106° and 107° for about six hours. Of 25 cases reported recently from the Mayo Clinic, 9 had been cured by one treatment, 4 by two treatments, and 3 by three treatments. It was important to recognise vaginitis due to the *Trichomonas vaginalis*, which might be mistaken for gonorrhœa and which seemed to be on the increase. It resisted all treatment except the application of Devegan. A similar condition might be found in the male urethra. Greater discrimination had been achieved in the soft chancre field. There were also some obstinate rectal inflammations, ranging from esthiomene to proctitis. It was important to apply skin tests at once to such cases. Intravenous Dmelcos was a useful form of treatment. If the condition did not yield to this and local applications, it was as well to think of granuloma inguinale and to give the specific antimony.

There had been a substantial and real decline in syphilis, and this disease was not being transmitted as freely as it used to be. The Ministry of Health Circular No. 1474 was a useful publication for all concerned with this work. The League of Nations had issued recommendations on the treatment of early syphilis which were likely to lead to a decided improvement. The recommendations had been based on an analysis of 13,000 patients in the primary and secondary stages. The treatment of merchant seamen who moved about from place to place was unsatisfactory, but the Office Internationale d'Hygiène publique were taking the matter up.

In the course of the subsequent discussion, the importance of taking rectal smears was urged; proctitis was often associated with vaginitis and no doubt accounted for many of the relapses. The head of the department of medical hygiene in Victoria (Dr. E. BRITTEN JONES) mentioned the fall in the number of cases of general paralysis of the insane in that State, and said that attention was being paid to the problem of mental deficiency in its relation to syphilis. He described a case of primary chancre of the lip treated by induced malaria alone, with apparent success. Mrs. A. E. WHEATEX (Adelaide) urged the establishment of an international dossier for every syphilitic treated, so that clinics to which he went subsequently could see exactly what had been done from the very first.

A report on the recent work of the Edinburgh venereal diseases clinic was submitted by Dr R. C. L. BATCHELOR. The Kline test had been studied; it seemed to be less reliable than the Wassermann in the earlier stages, but useful in assessing the result of treatment. He urged the establishment of a central bureau of information for malarial therapy. An attempt had been made to assess the influence of unemployment on the spread of venereal disease, but the sapping of physical and moral fibre seemed to be balanced by the organisation of clubs and other measures to help the unemployed. The measures designed to prevent ophthalmia neonatorum had not been completely successful, and practitioners, final-year students, and nurses might be circularised on the subject with advantage.

Major JEHAL SHAH (Bombay) submitted a paper on the treatment of acute gonococcal epididymitis, in which he emphasised the importance of adequate routine treatment to prevent resulting disability. The condition might be caused by the use of strong solutions or a reservoir placed too high when giving posterior irrigation for urethritis. Diathermy was of great value, and a few intramuscular injections of contramine at the proper time would facilitate results and minimise the risk of sterility. Daily intravenous injections of mercury cyanide and vaccines were also of great value.

Yaws and Syphilis

At the second medical session the chair was taken by Dr. HUGH STANNUS, who said that the problem of yaws and its relationship to syphilis was one of great magnitude. Most of those working in countries where yaws was common had little knowledge of syphilis, and vice versa, and as a result much confusion had arisen. Yaws was a far less serious affliction than syphilis: the primary sore was usually extragenital; the mucous membranes were not affected; itching was common and alopecia unknown. Yaws was never congenital, nor did it ever affect the eyes, viscera, nerves, or arterial systems. The conditions which favoured the spread of yaws and syphilis were not mutually exclusive. Yaws was a disease of the bush, and syphilis of the towns. Yaws did not protect from syphilis. In syphilis immunity appeared in six weeks; in yaws not for about six months.

Dr. P. H. MANSON-BAHR discussed the problem from the ecological standpoint. He did not adhere to the fixed idea that the two conditions were definitely separable. Anomalies of evolution were found throughout animal life, and were probably equally common among microbes. He suggested that yaws might represent a primitive form of syphilis among primitive people. With the advance of civilisation and clothing, contact inoculation became impossible, so that a strain of spirochæte evolved which could be conveyed by sexual contact. An analogy might be drawn with the relapsing fever spirochætes: organisms morphologically identical were transmitted through distinct arthropods to produce distinct clinical forms of the disease. In the tick-borne type there were marked neurotropic tendencies, which were not found in the louse-borne disease. The louse-borne forms seemed to be particularly amenable to salvarsan, to which the tick-borne types were resistant. There seemed no doubt that in the future it would be possible in the laboratory to convert one species of typhus virus into the other, and, if this could be done, there was no insuperable difficulty in the supposition that the spirochætes of yaws and syphilis might be interchangeable.

Major G. J. KEENE contributed his experience from Uganda, and said that there was much controversy and variety of opinion as to the differential diagnosis. It was important to know which was which, because of the great difference in treatment, in gravity of the disease, and in the cost of a large-scale campaign.

Social Hygiene in the Empire

In the course of the discussion on social hygiene problems within the Empire, papers were submitted by Dr. P. J. Kelly and Dr. B. E. Washburn respectively on the venereal disease problems of British Guiana and Jamaica. Dr. KELLY said that public opinion had definitely been aroused, but financial depression had held up schemes for treatment centres. In British Guiana, free treatment was confined to the principal clinic in Georgetown and subsidiary clinics at the county hospitals, but in the Windward Isles free treatment was available for all. The chief problems to be surmounted were ignorance, defaulters, continuous migrations in search of work, the prevalence of endemic yaws complicating statistics, and the great variety of races and cultures inhabiting the country. Dr. WASHBURN said that in Jamaica 10,600 patients had been treated during 1933 at the twenty public hospitals where free treatment was available. There was a regular scheme for health education and infant welfare. There was, however, no reliable information as to the incidence of venereal diseases in the island. Syphilis did not seem to be very prevalent. Many patients with gonorrhoea did not seek medical aid but, however widespread the disease was, it did not seem to cause crippling and serious trouble as it did in other places. Dr. L. J. Lemieux, adjutant-general for Quebec, presented a paper by Dr. A. S. DESLOGES on the provisions for dealing with venereal disease in the Province of Quebec. The educational campaign had, he said, resulted in a great increase of early cases, and an enormous amount of work was being done to combat syphilis and gonorrhoea.

The problem of the social worker in the venereal diseases clinic was discussed by Miss M. D. HEARN, assistant Lady almoner at St. Thomas's Hospital, at a session dealing with social services for women and children. The aim of the almoner, she said, was to establish friendly relations at the earliest possible moment, and many patients had told her that "they had not expected anyone to be kind to them in such a place." Many of the patients needed help in making readjustments to life. The diseases treated in these clinics had more social implications than any others, and an almoner was more urgently necessary than in any other department.

REVIEWS AND NOTICES OF BOOKS

Diseases of the Endocrine Glands

Third edition. By HERMANN ZONDEK, M.D. Berlin, Director of the Medical Division, Bikur Cholim Hospital, Jerusalem. London: Edward Arnold and Co. 1935. Pp. 492. 40*s*.

THE book is divided into two main parts. The first comprises a general survey of the functions of the endocrine system. Hormones are defined and their mode of action and inter-relationship explained. The physiology and chemistry of each hormonal gland is then studied separately; the comprehensive list of such glands including the thyroid, parathyroid, thymus, pituitary, sex glands, adrenal, pancreas, spleen, liver, hormones, pineal body, and carotid body; the so-called cardiac and circulatory are also discussed. The relationship between the hormones and vitamins, vegetative and central nervous systems, provide further chapters, and Part 1 of the book finishes with methods for the examination of patients for endocrine diseases. Part 2 is confined to a study of diseases or clinical entities associated with endocrine imbalance and each disease is treated separately. There are 22 chapters on Graves' disease, myxœdema, tetany, obesity, gigantism, dwarfism, osteitis fibrosa, hyperinsulinism, and so forth; in respect of each disease pathogenesis, etiology, symptomatology, and treatment receive full attention. A complete bibliography is given at the end and the references are grouped under the various chapters. Many illustrations, photographs, and charts further enhance the value of this work. Dr. Zondek has not tried to supply a compendium of physiological data, but rather to provide the clinician with a detailed study of the endocrine disorders. He has succeeded admirably. It is a stimulating work and deals impartially with old-established theories and recent views. Graves' disease is studied very fully, in exceptional detail. Dr. Zondek's work on this subject is already well-known; he has permitted himself to make certain definite statements on matters which are highly controversial—for example, that toxic cases without goitre respond better to potassium iodide alone than to Lugol's solution, and that digitalis does no good and may do definite harm to the heart in Graves' disease.

No small share of the credit for the production of this excellent book is due to the translator Dr. Carl Prausnitz.

Principles and Practice of Urology

By FRANK HINMAN, M.D., Clinical Professor of Urology, University of California Medical School. London and Philadelphia: W. B. Saunders Co., Ltd. 1935. Pp. 1111. 45*s.*

THE output of urological text-books by American authors continues; at least one new one seems to appear every year. In the preface to this latest addition to the American urological library an explanation of the multiplicity of American works on this subject is given. According to Prof. Hinman at least 40 per cent. of American medical graduates become specialists and another 40 per cent. of those who enter general practice give particular attention to one branch of medicine; since urology has now become an important specialty a large number of American practitioners are whole-hearted or half-hearted urologists.

Hinman's text-book differs in many respects from its predecessors, more especially in the prominence given to comparative anatomy, physiology, and pathology. The reason for his preoccupation with these subjects is the author's conviction that "the fundamental principles of urogenital practice are based primarily on anatomical conditions," and therefore can only be understood by one with an accurate knowledge of anatomy, including under this heading comparative anatomy and embryology. Unfortunately this attitude has involved the sacrifice of other matter of even greater importance to the practising urologist. After all, it is on the skill of his treatment that his success will depend, and in this work practical details of treatment have been badly scamped. It is of far greater importance to a surgeon to learn when a nephrectomy must be carried out and the best method of doing it, than to have a theoretical knowledge of the excretory apparatus of the fish. The paucity of space given to treatment is the more regrettable since the author is well known in the world of clinical urology and is one whose opinion on matters of practical importance would carry considerable weight. Even when these opinions run counter to those held by most experts they are stamped to carry the weight of wide practical experience. In spite of the shortcomings noted, this work contains a vast amount of interesting material, and provides a valuable supplement to other books of a more practical nature.

Krebs und Vererbung

By Prof. Dr. HANS R. SCHINZ and Dr. FRANZ BUSCHKE (Zürich). Leipzig: Georg Thieme. 1935. Pp. 280. R.M.21.

IN this book the authors have collected the numerous observations, scattered throughout the literature, which bear on the hereditary factors in cancer. They approach the subject from the point of view formulated by one of them (H. R. Schinz) in 1928 that cancer is a somatic mutation. The book begins therefore with a brief account of the gene theory of inheritance, which applies to mutations occurring in the germ-cells. The genetics of the incidence of tumours in such animals as drosophila, the mouse and the rat, and in man are then discussed. This section is followed by one on genetic factors determining the transplantability of tumours. The authors then deal with the experimental production of malignant tumours in animals and with the corresponding clinical phenomenon, occupational cancer in man, and they discuss the interaction of the two factors which determine the onset of cancer—namely, the extrinsic factor of chronic stimulation and the intrinsic factor of the genetic constitution. In this section reference is made to the filtrable fowl tumours. They do not readily fit into the picture of cancer as a somatic mutation, and these tumours are dismissed briefly in a page and a half by the suggestion that the filtrable agent is not a virus but a chemical substance. But even if one accepts that view it would have been of interest to know the arguments which would support the conception of chemical substances capable of producing in somatic cells immediately and without fail different specific mutations, all of which have in common that they confer upon the somatic cell the property of malignancy.

The least satisfactory part of the book are the statistical considerations of the incidence of cancer in man, which are based on the cancer mortality in the town of Zürich. A town of 250,000 inhabitants with a total cancer mortality of only 400 persons per annum can hardly yield suitable statistical material on which to discuss the incidence of cancer. The fact that the cancer mortality increases with age was surely known before 1932 when Schinz and Senti demonstrated this phenomenon also for Zürich. In speaking of an age disposition for cancer the authors do not even consider the view now held by many students of the cancer problem that the increase in the incidence of cancer with increasing age is not due to a special disposition of the aged organism for the development of malignancy, but rather to the long period of time necessary to induce cancer. No reference is made to the extensive work of von Pirquet where differences in the age-incidence of the various organs are discussed.

These are minor blemishes. Not only does the book contain a mass of interesting observations, but these have been well and clearly arranged and they are illustrated by 160 well-reproduced figures and diagrams, and there is a bibliography of 20 pages. If the book converts many readers to the view that cancer is a somatic mutation, it will also convince them that this conception is very far from being a short cut to the solution of the cancer problem.

A Manual of the Practice of Medicine

Thirteenth edition. By A. A. STEVENS, M.D., formerly Professor of Applied Therapeutics in the University of Pennsylvania. London: W. B. Saunders Co., Ltd. 1934. Pp. 685. 16*s.*

Stevens's Manual of Medicine is well known and popular in this country. His new edition appears six years after the last, and has additions which bring it fully up to date. For so small a book it is indeed remarkably complete, and though it makes no pretence to be more than a student's handbook, it must be regarded as an unusually comprehensive one. Stevens's medicine has certain advantages not always shared by the smaller text-books of medicine. The student who reads it well is less likely to put the rare causes first and to lose his sense of proportion, or to deprecate the importance of clinical observation than one who pins his faith to some of the other manuals, and he may even be inspired to seek fuller knowledge from another source. It is almost impossible for a teacher to express his personality in such a book as this, but so far as this can be done, Dr. Stevens has succeeded. His style is clear and concise; the arrangement of the book is good and the cross-references accurate; the index might perhaps be a little fuller. Treatment is given a prominent place, and a large number of prescriptions are included. This little book will continue to be welcomed by the student, and need not be despised by those who have satisfied the examiners.

Health, and a Changing Civilisation

By E. Obermer, M.D. London: John Lane, The Bodley Head, Ltd. 1935. Pp. 171. 3*s.* 6*d.*

This book is written for the general public, but it is very largely about the present form of medical practice, its preoccupation with disease and its failure, so far, to apply physiological knowledge to the promotion of individual health. The author holds that the human race has not adapted itself to a rapidly changing civilisation, and that the individual man is therefore less healthy than he was. It cannot be said that he attempts to prove this basic contention, but he finds its physiological explanation in imbalance of the neuro-endocrine-circulatory system. Changes in medical education, medical practice, and the public attitude to medicine are advocated, and a plan for an individual health service is outlined. It is only fair to add that the author does not expect these changes to be brought about quickly, but he hardly seems to realise the extent to which the public health service—in his view an organisation merely for preventing disease—is ready to absorb and utilise such knowledge as is available for promoting vigorous health, and the extent to which it is ready to contribute to investigation in such matters. The book is written with enthusiasm, and expresses a point of view which is not uncommon among those younger members of the profession who are dissatisfied with present-day medicine.

Insomnia and other Disturbances of Sleep

By Emanuel Miller, M.A. Cantab., M.R.C.S., L.R.C.P., D.P.M., Psychiatrist, West End Hospital for Nervous Diseases; Physician, Institute of Medical Psychology; Hon. Director, East London Child Guidance Clinic. London: John Bale Sons and Danielsson Ltd. 1935. Pp. 88. 2*s.* 6*d.*

Dr. Miller handles his subject in a suggestive way. His keynote is the value of balance. He holds that in satisfactory living equilibrium is an essential factor, and that sleep and wakefulness are the positive and negative poles of such living. His views are certainly expressed with an understanding which the reader feels to be based on such an equilibrium, for he deals with insomnia sympathetically from the standpoint of the psychical and the physical, theory and practice, causation and treatment, in the short space of some eighty pages. An interesting feature is his reference to Mengazzini's theory of the activity of the endocrines in the production of sleep and waking and of the share which the vegetative nervous system may have in the disorders of sleep; he hints that these factors are often associated in the sleep disorders of childhood and may sometimes explain such difficult problems as enuresis and night terrors.

The discussion of insomnia in the absence of any physical cause, such as pain or disturbed digestion, is of real interest. Such disturbances seem to resolve themselves into the fears and preoccupations of an anxious mind, whether they become evident through the dream of the normal, the somnambulism of the neurotic, or the waking hallucination of the psychotic. From the chapters on treatment much useful information can be collected in terms of general measures, drugs in their varied forms and psychotherapeusis. An excellent little bibliography is appended.

Physical Chemistry

For Students of Biology and Medicine. Second edition. By David Ingersoll Hitchcock, Ph.D., Associate Professor of Physiology in the Yale University School of Medicine. Springfield, Ill.: Charles C. Thomas; London: Baillière, Tindall and Cox. 1934. Pp. 214. 12*s.* 6*d.*

This volume is a worthy addition to the long list of books which have been the outcome of the attempt to teach physical chemistry to medical students. In these books the preface usually contains a despairing allusion to the state of ignorance of the student, a hint that this makes the writer's task extremely hard, and a modest hope that success has been achieved. The book now under review covers the ground adequately and has the advantage of possessing a good bibliography. The subjects are treated in a fairly non-mathematical manner, but it is to be feared that the author has assumed in his readers more basic knowledge than the English medical student as yet possesses.

Medical Case-taking and Diagnosis

By A. J. Kohiyar, B.A. Bom., M.D. Lond., M.R.C.P. Lond., Hon. Physician, J.J. Hospital, Bombay; late Professor of Biology, Grant Medical College, Bombay. Bombay: The Medical Bulletin. 1935. Pp. 133.

This is a short manual in which the orthodox methods of history-taking and physical examination are simply and attractively set forth, and the accompanying incidental information about disease and its manifestations is sound, useful, and not overburdening. Although the author is writing ostensibly for Indian medical students, we find no special mention of tropical conditions except in one chapter on the differential diagnosis of fevers, and we are tempted to ask why this book should be offered in place of the standard English books. One reason may be that it is shorter and simpler. Another is that the author wishes to emphasise the importance of systematic physical examination by omitting altogether the laboratory methods. He leaves these —including even urine examination—to be dealt with elsewhere, and gives all his space to history-taking and the searching of the patient's body by the examiner's eyes and hands and ears. There is much to be said for this attitude: if the Indian student masters the methods here set forth he will have laid a good foundation.

Commonsense Dentistry (a National Necessity)

By Edward Samson, L.D.S., F.C.S., Honorary Dental Surgeon to the Royal Victoria and West Hants Hospital, Bournemouth. London: J. S. Cottrell and Co. 1935. Pp. 100. 7*s.* 6*d.*

This book consists of three chapters, two of which are alliteratively named the Caries Chaos and the Pyorrhoea Panic. Mr. Samson makes some shrewd and witty hits at the confusion which reigns with regard to the ætiology and prevention of caries and pyorrhœa. The first chapters in which Mr. Samson pours ridicule on the theories concerning caries and pyorrhœa are funny in places, though perhaps not quite so funny as they are intended to be. In the last chapter entitled Common-sense Dentistry, with a portentious sub-title, "the birth of a new idea," Mr. Samson purports to provide a remedy for the lack of precise knowledge as to how dental disease is caused. He seems to think that if the government instituted a national laboratory for investigating dental caries and pyorrhœa all would be well and that the problems of causation and prevention would be speedily solved. All that is required, according to him, is for the Minister of Health to appoint a committee which should consist of the Minister himself, his chief medical officer, a public dental surgeon, a practising dental surgeon, a member of the Medical Research Council, and a member of its subcommittee on dental disease, together with any dental surgeon or other person whom the committee thinks would be useful. This committee would investigate the various reputable (sic) theories, correlating them according to their class and probability as advised by their professional members, apparently the dental surgeons. It would also gather statistics and, as the result of its labours, produce a report containing a line of action for the tame scientists herded in a government laboratory of dental research, who would then proceed to make discoveries which would solve the knotty problems of how dental disease is caused and how it may be prevented. How easy it sounds!

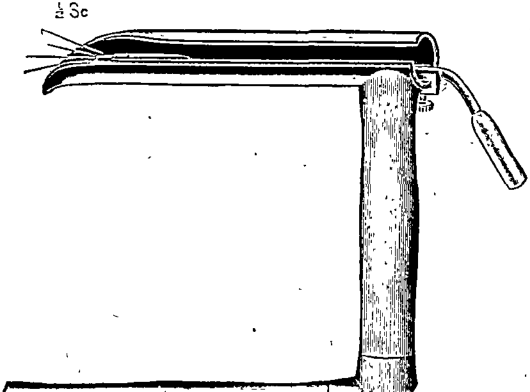
NEW INVENTIONS

ENDOTRACHEAL INSUFFLATION OF THE NEW-BORN

Messrs. Down Brothers, of London, have made for us the apparatus necessary for intratracheal insufflation of an O_2-CO_3 mixture in the treatment of asphyxia neonatorum as described in THE LANCET of March 30th, 1935 (p. 736).

The direct vision pharyngoscope illustrated (Fig. 1) is a modification of Howarth's Chevalier Jackson's instrument which has been designed for use in the new-born infant. The speculum is 10 cm. long, and its greatest outside diameter is 1·6 cm. The spatula is very short so that the soft palate does not obstruct the line of vision. The handle of the instrument is parallel to the speculum and joined to it by a shank 11 cm. long. This parallel handle gives better control than one set at a right angle to the speculum, and a shank of 11 cm. gives sufficient clearance between the handle and the chest wall during use. A wide infero-lateral slot runs the entire length of the speculum so that the pharyngoscope can easily be withdrawn without displacing the catheter when the latter has been introduced into the trachea. The illumination is by a lamp situated at the distal end, and the current is supplied by a battery enclosed in a separate wooden box with a variable resistance. In practice this arrangement of having a large separate battery has been found to be very satisfactory, since a dry cell purchased eighteen months ago is still in use by one of us.

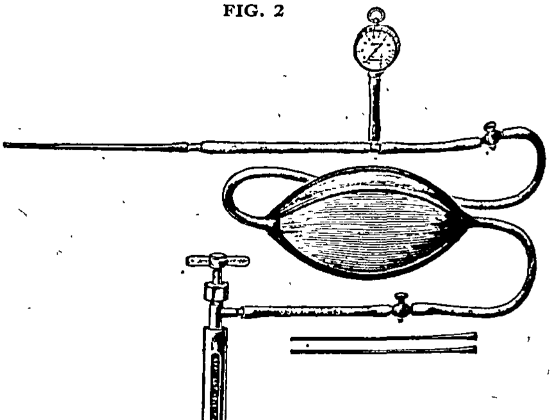
FIG. 1



The catheter used is a Magill's silk-web endotracheal catheter with a funnel-shaped end. Sizes 3, 4, and 5 give a suitable range. The choice between these sizes is determined by the size of the infant.

The apparatus (Fig. 2) for delivering the O_2-CO_2 mixture (90–95 per cent. O_2 and 5–10 per cent. CO_2) consists of a rubber bag of 3000 c.cm. capacity fitted at one pole with an inlet tube which can be connected to the supply of gas, and through which the bag can be filled. A tap on the inlet tube allows the bag to be disconnected from the supply of gas if necessary so that it can be kept in readiness in a convenient place, after having been filled. At the opposite pole of the bag is the outlet tube also furnished with a tap. This rubber tube is about 2 ft. long and terminates in a conical glass connexion which is easily connected to the funnel-shaped end of the endotracheal catheter after the latter has been introduced through the direct vision pharyngoscope. By means of a metal T-piece an aneroid manometer is attached to the outlet tube near its exit from the bag. This manometer has been specially made to register pressures within a range from 0 to 50 cm. of water.

FIG. 2



By compressing the bag with the hand the gas can be forced through the endotracheal catheter at any desired pressure, and any variations in pressure are immediately recorded on the manometer. The pressure required in the bag is usually 30–35 cm. of water, since this is sufficient to produce a pressure of about 15 cm. of water in the lungs themselves, provided a suitable size of catheter is chosen, depending upon the size of the infant. If necessary the bag can be continually refilled without interrupting the process of insufflation. The whole apparatus is compact and can be easily carried in the midwifery bag.

G. F. GIBBERD,
J. B. BLAIKLEY.

THE LANCET

LONDON: SATURDAY, JULY 20, 1935

ARTIFICIAL RESPIRATION ON THE SPOT

RESPIRATORY failure is the commonest mode of death, and artificial respiration is one of the three principal means of overcoming it, the others being inhalation therapy and the use of drugs. The method adopted may be either manual or mechanical, and the past few years have seen big advances in the evolution of apparatus designed to ventilate the lungs and to keep the respiratory mechanism working. The Drinker-Shaw respirator and the Bragg-Paul pulsator, for example, have both proved of great value where artificial respiration has to be maintained for very long periods; they have been used with success in Landry's paralysis and in the paralysis following poliomyelitis and diphtheria, as well as in cases of poisoning by carbon monoxide and by narcotics, and in cases of electrocution, apparent drowning, and asphyxia neonatorum. Complicated apparatus cannot, however, be applied rapidly outside hospital, and most of the accidents in which artificial respiration is urgently needed take place in the street, on the seashore, in the workshop, or in the power-house—that is, in places far removed from the most up-to-date instruments for expert medical treatment. Hence the proper use of manual methods is of first importance.

Of the many manual methods available, the two most popular are those of Silvester and Schäfer. Before SILVESTER brought his forward in 1858 those in use were crude and unsatisfactory. Thus H. W. RIVERS,[1] writing in 1845, says that—

> "the best mode of artificial respiration is by inflating the lungs from the breath of another person, or by means of a pair of bellows, . . . the pipe of which should be introduced into one nostril, and the other, as well as the mouth, should be closed. The bellows should then be put gently in motion until the lungs are inflated, which may be known by the breath's being fuller than when the operation was commenced."

And he goes on indignantly to point out that "the vulgar, inhuman and unphilosophical practice of rolling a party labouring under asphyxia, from drowning, on a barrel, or suspending him by the feet, needs only to be mentioned to be condemned." To-day, 90 years later, our outlook on the problem is or should be founded on a more scientific basis. In our present issue Dr. C. J. MIJNLIEFF sets forth four requirements which a manual method of artificial respiration must meet. First it should secure sufficient ventilation of the lungs; secondly, this ventilation should fulfil its primary purpose of facilitating exchanges of blood gases in the pulmonary circulation; thirdly, the nutrition of the heart must be promoted in order to maintain both the pulmonary and the systemic circulations; and finally, the application of the method must not injure the patient. With these requirements all will agree; but do they go far enough? We would add that any form of artificial respiration which is to be widely recommended should be easily learnt by unskilled workers and easily applied. Experimental work by various investigators shows that Silvester's method gives better ventilation of the lungs than those of Howard and Schäfer, since it aims at the rhythmical increase and decrease of the negative pressure in the thorax; and it is this negative pressure which brings about distension of the air cells and the blood-vessels surrounding them and helps to promote the blood flow in the pulmonary circulation. From the anatomical and experimental standpoint Dr. MIJNLIEFF is able to make out a good case for preferring it to that of Schäfer. It is well to bear in mind, however, that the forced expiration initiated in Schäfer's method brings in its wake a not inconsiderable negative pressure, due to the inherent resilience of the pulmonary tissues, the pleural membranes, and the thoracic wall. The state of equilibrium of the extensively distributed elastic tissue in the thorax is inconsistent with either forced inspiration or forced expiration.

At the fourth international Congrès de Sauvetage et de Secours held at Copenhagen last summer a number of manual methods were described and strongly advocated. On the whole English, American, and French medical opinion favoured Schäfer's, but the German and Dutch schools condemned it strongly and stood by Silvester's or its modifications. Prof. STEFAN JELLINEK[2] advanced an interesting method of his own.

> The patient is placed on his back with a pad between the shoulder-blades. The fingers of the patient's own hand are placed on his tongue, and fixed in position by a bandage round the wrist and neck. This manœuvre prevents the tongue from falling back over the glottis. The shoulders are then pushed down, or, as Jellinek says, folded back over the pad between the shoulders, and then allowed to return, to their original position. In this way the volume of the thorax is increased and decreased rhythmically.

He claims that this procedure is distinguished from all others by the fact that it is based solely on a folding action and not on compression or traction. His main objection to Schäfer's method is that, in experimental animals, compression of the chest brings about œdema of the lungs and brain. If in reply we argue that it is not always possible to infer from animal experiments that similar conditions would arise in man, this argument only lends force to JELLINEK's statement that research on life-saving and reanimation is not sufficiently widespread. The two main questions to be answered are: what method should be taught to first-aid workers and unskilled workmen who have to deal with an unconscious comrade, and what methods should medical practitioners be able to apply or supervise? It seems reasonable that the unskilled worker should be taught the simplest, but there is no need for the doctor to be limited in his choice. Schäfer's method is taught by the St. John Ambulance Association, which recommends Silvester's only when it is inexpedient or impracticable to turn the patient on to his face; and there does not seem to be sufficient reason why a method used with success by first-aid workers should be abandoned by them. But medical practitioners might be more eclectic. As Hederer[3] points out, cases of asphyxia fall roughly into three groups: (1) Asphyxia from drowning, in which the respiratory passages are partly or wholly obstructed by water or froth. Here, and wherever there is œdema of the lungs, Schäfer's method is probably the most useful, because the position of the patient and the compression of the chest help to empty the bronchial tubes. (2) Asphyxia from poisonous gases, in which the respiratory passages are often clear. Here the methods of Silvester or Jellinek might be used with advantage. (3) Syncope or "white asphyxia," in which there is some inhibition of the respiratory centres in the brain. Here the method which will probably give the best result is Silvester's or a modification of it, combined with rhythmical traction of the tongue.

[1] Rivers, H. W., "Accidents—Popular Directions for Their Immediate Treatment," Baltimore, 1845. Quoted from The National Safety News, May, 1935, p. 20.

[2] Jellinek, S.: Bruxelles méd., Feb. 17th, 1935, p. 432.

In accidents due to electric shock it is observed that artificial respiration, started by the victim's associates, often stops as soon as a doctor arrives on the scene. Yet in these cases prolonged artificial respiration is the one essential form of treatment, even when signs of life are not obvious. In many factories resuscitation apparatus, consisting of a mask and cylinders of oxygen and carbon dioxide, is available, and when possible artificial respiration should be combined with the administration of this mixture of gases, which has a valuable stimulating effect on the respiratory centre. But with or without apparatus, artificial respiration must be maintained, and all things considered it seems that Schäfer's method will be the most appropriate variety. After clearing out the mouth and throat the first-aid worker can feel sure that this part of the air-passages will be free, whereas with Silvester's method the tongue has to be held up and the angle of the mandible pushed forward—small and important details which may be neglected by unskilled workers in the heat of the moment. Schäfer's method is easily taught and easily learnt and if it is performed carefully at a proper rhythm the patient will not be injured. But in cases of electric shock, whatever form of artificial respiration is adopted, it should be carried out by a team of workers for not less than eight hours, if automatic respiration has not previously been established. It is better to waste effort on a dead man than to lose a chance of bringing back a life which is only suspended.

URINARY INFECTION

There is now general agreement that the introduction of the ketogenic diet has greatly improved the prognosis of chronic urinary infection. In a recent critical review of 150 cases treated at the Mayo Clinic E. N. Cook and W. F. Braasch[1] say that this diet was successful in curing 85 per cent. of the uncomplicated cases. In the presence of any form of obstruction, however, the diet, while relieving symptoms, often failed to sterilise the urinary tract. This is only to be expected, since any obstruction to the outflow must lead to retention, and infection of the stagnant urine will follow almost inevitably. Unless the obstruction is removed the infection may persist despite any form of treatment. The importance of this factor and of a search for some underlying cause in every case of chronic urinary infection is emphasised by Prof. A. W. M. Ellis *on another page of this issue.* The cases described by him illustrate some of the forms of obstruction to the urinary outflow which may be found in chronic pyelitis; they also serve as an effective demonstration of the value of intravenous pyelography in routine investigation. It is noteworthy that the ketogenic diet is not equally lethal to all types of organisms found in urinary infections; it appears to be most useful in cases infected with coliform bacilli. These organisms, which account for approximately 80 per cent. of all urinary infections, can be subdivided by their biochemical reactions into two main groups: the *Escherichia coli* (*B. coli*) and the *Aerobacter aerogenes* (*B. lactis aerogenes*). Of 200 cultures of Gram-negative bacilli isolated from the urinary tract and studied by J. H. Hill and co-workers,[2] 100 were found to fall into the former group, while 79 belonged to the genus aerobacter. The two groups differ greatly in their resistance to drugs and also in their reaction to the ketogenic diet,[3] the aerogenes group being the more resistant.

The ketogenic diet as a practicable therapeutic measure has been justly criticised on the grounds that it is unpalatable, that it cannot always be tolerated, and that, since it requires the assistance of a skilled dietitian and a continuous and rigorous supervision of the patient, it is only suitable for treatment in a hospital or nursing-home. Clark and B. F. Keltz[4] have devised a simplified form of the diet, something on the plan of R. D. Lawrence's line rations for diabetics, which, they hope, may make it possible to treat coöperating patients in their own homes. But while some patients of education and fortitude living at home may and actually do adhere strictly even to the ketogenic diet now in use, it seems doubtful whether the ordinary out-patient will ever be persuaded to persist for 10 or 12 days without an occasional indiscretion with a diet which may be simpler to plan but is no more palatable. It must be remembered that even a single dose of a sweetened cathartic contains sufficient carbohydrate to upset the ketogenic-antiketogenic balance. CLARK and KELTZ hold that several short courses of dietary treatment are preferable to one long one and that whether or not the results have been satisfactory a mixed diet should be resumed after 12 days. Here again is a source of difficulty; it is mainly the hope of a more or less permanent cure without another course of treatment that induces patients to keep to the rules.

---

[3] Hederer, C., quoted by Sillevaerts, C.: Ibid., 1934, xv., 131.

[1] Jour. of Urol., 1935, xxxiii., 583.

[2] Jour. of Bact., 1929, xvii., 205; Jour. Amer. Med. Assoc. 1935, civ., 1186.

[3] Clark, A. L.: Jour. of Urol., 1934, xxxi., 193.

[4] Jour. Amer. Med. Assoc., 1935, civ., 289.

Not long after the introduction of the ketogenic diet A. T. FULLER[5] showed that the effective agent in the urine of patients under treatment was one of the keto-acids, β-hydroxybutyric acid. This acid was found to exert a bactericidal action in vitro below pH 5·5, and it has since been shown that if the treatment is to be successful, a minimum concentration of 0·5 per cent. of the acid must be obtained in a urine of low pH. β-hydroxybutyric acid cannot normally be given by mouth to control urinary infections, since it is completely oxidised unless the patient is in a state of ketosis. It has been administered orally both by FULLER and LEONARD COLEBROOK[6] and by COOK and BRAASCH (loc. cit.) to reinforce the effect of a dietary ketosis. A few weeks ago we published a paper by Dr. M. L. ROSENHEIM[7] advocating the use of mandelic acid as a substitute for the ketogenic diet. This acid, like other organic acids allied to β-hydroxybutyric acid, was found not only to be bactericidal in vitro to coliform bacilli but to be non-toxic; but unlike many hydroxy-acids, after oral administration it was excreted unaltered in urine which was rendered bactericidal. Mandelic acid has been used with promising results in the treatment of a small series of cases of urinary infection at University College Hospital and is, we understand, receiving a more widespread trial. In order to obtain the effective concentration in the urine (0·5–1 per cent.), it is necessary to give the acid in large quantities (12 grammes a day). Since this dose may act as a mild renal irritant, a careful watch must be kept for any increase of albumin and for casts in the urine. Mandelic acid, like β-hydroxybutyric acid, is only active at a low pH and this can conveniently be produced by the simultaneous administration of ammonium chloride. Mandelic acid treatment evidently demands the same careful supervision of the patient as does the ketogenic diet. But those who have either had personal experience of this nauseating diet, or have acted as dictator to one who is confined to it will welcome the possibility of attaining equivalent results by the use of a drug not unpleasant to take. This new treatment is the logical outcome of the recognition of β-hydroxybutyric acid as the active agent in the urine of patients on the ketogenic diet, and we hope that further clinical experience will show that it can effectively replace dietary measures in the treatment of chronic infections of the urinary tract.

HERD IMMUNITY

THE experiments with mouse herds of W. W. C. TOPLEY and MAJOR GREENWOOD at the London School of Hygiene and Tropical Medicine are gradually lending precision to our understanding of epidemic and endemic events. In a paper read at the congress of the Royal Sanitary Institute at Bournemouth on July 16th, Prof. TOPLEY indicated some of the conclusions to which the work is pointing. He suggested the following definition of herd immunity: "The immunity of any herd in relation to any infective disease may be expressed inversely in terms of the rates of morbidity or mortality induced by the exposure of that herd to the risk of infection with the causative organism of the disease in question." Herd immunity may be of two types: (*a*) dependent upon the social or biological structure of the herd, being non-specific and due to conditions unfavourable to the transmission of infection; and (*b*) dependent upon the individual immunity (of some or all of the herd members) resulting from natural infection or from artificial immunisation. Such immunity is narrowly specific in its action. It is owing to the vulnerability to attack of the agents carrying the intestinal and insect-borne infections that a herd immunity of the former type has been acquired to such diseases as cholera, plague, and typhus. The droplet infections, on the other hand, are limited in their spread only by the immunity which individuals have acquired by clinical or subclinical reactions to them.

In the experiments of TOPLEY and GREENWOOD immunity of type (*a*) is eliminated, and the behaviour of infectious diseases is observed in a community of mice, more or less constant in population, of whom some of the initial group are deliberately infected and the casualties are replaced by susceptibles. It has been found possible to maintain such artificial centres of disease for several years, the rate of addition usually being three mice a day. The infections used are mouse typhoid, pasteurellosis—resembling pneumonic plague—and a virus disease, ectromelia. During the first few months of such an experiment there tend to be waves of mortality, but later the death-rate usually settles at a steady level if the rate of daily additions is sufficiently high. This state of affairs, artificially induced, indicates, it is suggested, that the epidemic process, when fully established under conditions which allow free spread of infection, has no inherent factor that imposes periodicity, or, indeed, any wave-like movements of mortality. The average expectation of life limited to 60 days in a healthy herd recruited at the same rate (three mice a day) is about 58 days. In herds infected with disease, new entrants have about half this normal expectation, falling to about a quarter or two-fifths at the end of 10 to 20 days, and then gradually improving until those that have survived for 50 days have 70 per cent., and those that have survived 100 days 80 per cent., of the normal expectation of life. The death-rate (the probability of dying within five days) rises rapidly to the twenty-fifth day of cage-age and then tails away. It is believed that the better resistance of the surviving mice is mainly acquired by sublethal infection and is not genetic in origin.

---

[5] THE LANCET, 1933, i., 855.
[6] Ibid., 1933, ii., 735.
[7] Ibid., 1935, i., 1032.

"When an infected herd is formed," says Prof. Topley, "there is a rapid spread of infection, associated within a few weeks with a wave of mortality. The majority of the new entrants are infected soon after entry to the herd; half of them within a fortnight, 80 per cent. or more within a month. During the earlier stages of the epidemic the mice at risk are in part being killed by the prevailing disease, in part being immunised by sublethal infections. This early stage is marked by a widely fluctuating death-rate, or in some cases by separated waves of mortality. Later, as the total population increases, it becomes differentiated into sub-groups of varying cage-age, and consequently of varying resistance. Finally, a condition of equilibrium is attained, in which a steady average death-rate, derived from different death-rates operating on the different cage-age groups, combines with a steady rate of immigration to produce an invariant total population."

Topley and Greenwood have tried to influence this course of events by immunising mice before admission to the infected herds. In mouse typhoid the epidemic was not modified in its course, but the individual mice had a slightly improved expectation of life. With ectromelia, however, an attenuated virus had a much more striking effect. Immunised entrants artificially acquired as good a chance of survival as the old members of an infected herd and not much less than that of the normal uninfected.

Prof. Topley is cautious in applying these results to the practical problems of hygiene. They are in accord with the view that natural immunisation by clinical or subclinical infection, combined with the rate of accumulation of susceptibles in a community, is the most important single factor in determining the form of the endemic-epidemic prevalence of human disease which is provided with ample channels of natural spread. As regards artificial immunisation, they agree with the common experience that vaccination against a virus disease tends to be far more effective than vaccination against a bacterial disease of the invasive type; but no opportunity has been afforded for testing the effect of pre-immunisation against toxæmic types of bacterial disease like diphtheria and scarlet fever. The work on ectromelia at least supports the case for vaccination against small-pox (if any further scientific support was needed) and holds out hope that influenza may yet become controllable as the result of the work of Sir Patrick Laidlaw and his colleagues. Something is lacking in all antigens used for promoting immunity to the enteric group, and with Prof. H. Raistrick, Prof. Topley is attempting to find one which is more effective in mouse typhoid. As to the droplet infections, the fact that these appear to be insusceptible to any other method of control except pre-immunisation may bring disappointment to some, but should at least lead to much greater coöperation between public health departments and laboratories in carrying out field investigations.

ANNOTATIONS

DUFFERIN FUND JUBILEE REPORT

The Dufferin Fund, which has been selected as one of the four benevolent organisations in India to benefit by the Silver Jubilee Appeal, celebrates its own jubilee this year. The fiftieth annual report of this national association for supplying medical aid by women to the women of India describes the work for 1934 of the Dufferin Fund proper and includes that of the Women's Medical Service subsidised by the Government of India. The income of the former, though sadly diminished by the fall of interest on invested funds—succeeded in maintaining the usual twenty-seven scholarships to enable selected women medical students to study and qualify in 5 Indian universities, and in subsidising various women's hospitals in different provinces. The total number of women students taking the University courses was 367. There are also 593 women studying medicine in various medical schools throughout India. At the Lady Hardinge Medical College, New Delhi, 152 women students are in residence, drawn from 22 provinces and states and of 9 different races and religions. The course is spread over seven years, two of which are pre-medical. Nine members of the Women's Medical Service are deputed to this college as teaching staff and medical officers in charge of the various units of the hospital attached to the college. This hospital contains 220 beds and 56 cots; 4376 in-patients and 18,046 new out-patients were treated in 1934 and 2600 operations were performed; of these 215 were abdominal sections—59 being Cæsareans. The surgeon in charge of the surgical unit pleads for more radium in a form suitable to the treatment of carcinoma other than that of the uterus; the supplies at present available can only be used for this purpose. The reports of almost all the other 27 hospitals staffed by members of the Women's Medical Service form depressing reading.

Whilst most valuable medical work is clearly being done in these institutions, the difficulties with which the staff have to contend must be discouraging in the extreme: antiquated buildings and equipment, inadequate provision of absolute necessities, such as drugs, instruments, bed linen; poor housing conditions for an underpaid staff. Lack of funds is evidently hampering the work to an extent which would not be tolerated by public opinion in this country. There are now 41 full members of the Women's Medical Service, 21 of whom are of Indian domicile; 8 members are on probation and there is a reserve of 12 graduates of Indian universities in training. One development during the year under review is the appointment in London of a medical adviser to the United Kingdom branch of the Countess of Dufferin's Fund. Dr. Agnes Scott, who was chosen as the first holder of this office, is a former chief medical officer of the Women's Medical Service, can be consulted on Monday afternoons or Thursday mornings, at India House, Aldwych, where, through the courtesy of the High Commissioner for India, she has been given an office.

VITAMIN STANDARDS

AT the request of the Health Organisation of the League of Nations, the board of trustees of the United States Pharmacopœia have consented to make generally available the standard cod-liver oils prepared for use in the United States as secondary standards for vitamins A and D. The distribution of these oils will not be made through the national distributing centres, as in the case of the primary Vitamin Standards, but direct to individual users. They may be obtained from E. Fullerton Cook, Ph.M. (chairman of the Committee of Revision of the U.S. Pharmacopœia), 43rd Street and Woodland-avenue, Philadelphia, Pa., U.S.A. It should be clearly stated whether Vitamin A oil or Vitamin D oil is required. A charge of 2·50 dollars is made for containers holding 30 c.cm. A sum to cover the cost of the quantity required should be sent by international money order with the application. The oils will be sent post free to their destinations. These reference oils are checked each six months biologically against the International Standards by at least six laboratories and their potency should therefore be increasingly dependable.

ACTIVITIES AT THE COLLEGE OF SURGEONS

FIVE years ago the Royal College of Surgeons of England opened a few small laboratories for experimental surgery and allied problems in the college buildings at Lincoln's Inn-fields, London. Three years later a surgical research farm, the gift of Sir Buckston Browne, was opened at Downe, Kent. That the opportunities for research which were provided are not being neglected is well seen from a study of the annual report of the conservator of the museum and director of research, Dr. John Beattie, which has just been published. The subjects of investigation range from purely surgical problems—e.g., surgical shock, wound healing, nerve grafting, intestinal obstruction and peptic ulceration—to fundamental physiological problems concerning the nervous mechanisms involved in the control of visceral functions. On Feb. 2nd the contributions of two of the research workers on the development of surgical shock were reviewed in these columns, and it was then pointed out that investigations such as these provide the necessary basis for a proper treatment of shock. From this present report it appears that further progress has been made in an understanding of the nervous factors which are concerned in the production of the "shock" condition. As the result of another investigation a new treatment for achalasia of the cardia has been well established and proved its value in practice, though a proper assessment of the final results cannot yet be made. Another subject of inquiry has been intestinal obstruction, which still has too high a mortality even in the most experienced hands. Various theories have been advanced to explain this, but the experiments of two of the investigators at the college have demonstrated the presence of a toxic substance which is apparently responsible for the deaths of their animals, even when the strangulated loop was released at a time when it was still viable. The toxin is produced in the gut-wall and is liberated into the veins, lymphatics, and later into the peritoneal fluid. These results suggest that excision of a strangulated loop is a much more rational procedure than a simple release of the strangulation.

The recent development of surgical research at the college is going on parallel to a series of developments in the Hunterian Museum which will increase still further the value of the collections housed there. A new section of surgical anatomy is planned. This is to contain dissections illustrating operative approaches to every region of the body. It is pointed out that such a programme will take years to complete, but even in its early stages it is bound to be of the utmost value to every young surgeon and to most experienced operators. The pathological catalogue is to include photographs of the histological appearances of the specimens on the shelves, and microscopical slides are to be made available to students. These are much needed improvements and will be appreciated by every student who uses the collection. In time the college will become the possessor of a collection of type tumours with complete data on the case-history, operative and other treatment, histology and after-history Such a collection, properly indexed and documented, should be a national one available to every pathologist in the United Kingdom.

The council is to be congratulated on the encouragement it has given and continues to give to the forward movement in the various scientific departments at the college. It is apparent that these departments are worthy of better accommodation than they possess at present, and it is to be hoped that means will be found to carry out the scheme of expansion which is outlined in the present report.

STATISTICS OF NOCTURNAL ENURESIS

BED-WETTING is a common and troublesome problem for which despite innumerable theories of causation, and consequently of treatment, there is no certain cure. Not infrequently the habit will disappear at an early age for no obvious reason. This absence of any exact knowledge has led the Child Guidance Council, founded in 1927, to an attempt to replace generalizations by some carefully collected statistics, designed to ascertain whether in certain characteristics the enuretic child differs from the non-enuretic. Material was obtained from the case records of six Child Guidance Clinics in London, all the 1705 new cases attending the clinics in 1932 being chosen. Such cases are not, of course, representative of all children since they have been referred to a clinic because they are difficult or nervous but this selection, applies to both the enuretic and non-enuretic groups. The collection and analysis of this material has been carried out by Robina S. Addis.[1] Of the total 1705 children, she reports 18·4 per cent., or nearly one-fifth, were enuretics, the proportion amongst boys (20 per cent.) being slightly higher than the proportion amongst girls (16 per cent.). In age they are, on the average, significantly younger than the non-enuretics—which might support the popular belief that a child "grows out of" the symptom. The non-enuretics are referred to the clinics in increasing numbers up to fourteen years of age while the enuretics show their peak at 8–10 years and then decrease. Position in family shows no significance, but there is a slightly lower proportion of enuretics among only children than in families of two or more. Calculation of the intelligence quotients leads to very similar average values for the enuretic and non-enuretic groups but the latter show rather more variability and there are less enuretics at the two extremes of intelligence. Enuresis is found to be by no means an invariable symptom of feeble-mindedness, not even on the idiot level, for there were thirty-two children with I.Q.'s of 40 and 50 who were not enuretic and only two who were. This, besides suggesting that bladder control is not a function of the intelligence points, the author thinks, to the conclusion that the constitutional and psychological factors predominate. She suggests that from her figures it may be deduced that the enuretics fall into two groups, the one of *high*, the other of *low normal intelligence*, and that this is in keeping with clinical observation which has shown two main types with lack of bladder control—the slow and lethargic and the restless and anxious. In view of the relatively small number of enuretics involved in this inquiry the validity of this deduction appears very doubtful.

INJURIES TO THE FACE AND JAW IN WARFARE

THE coöperation of the dental surgeon with the specialist in plastic surgery has greatly increased the possibility of successful treatment of wounds of the face and jaws. The patient's future often depends on whether mutilation is prevented and function restored, and wonderful as are the results of operations for the repair of wounds and deformities of long standing, it is still true that mistakes in the early stages of treatment may destroy the chance of satisfactory restitution. An Army advisory committee appointed to inquire into the facilities for the treatment of maxillo-facial injuries in modern conditions of warfare, has just issued its report to the Army Council,[1] and this lays emphasis on the importance of skilled dental treatment from the time the patient first enters the main dressing-station until he reaches the home hospital. A general hospital of 600 beds should, it is proposed, have one dental officer, one clerk orderly, and one dental mechanic, and a dental officer should also be detailed to every hospital ship whose voyage may last more than two or three days —all dental officers receiving a three months' course of training in the treatment of maxillo-facial injuries. Specialised surgery does not ordinarily come into the picture until the patient has reached the home hospital, but attention is drawn to points of importance in the first-aid and preliminary treatment. The danger of suffocation and of severe hæmorrhage may be largely overcome by correct posture, and by control of the tongue—a fact with which stretcher-bearers should be familiar. The prone position, with the head hanging over the end of the stretcher, is recommended. In the preliminary surgical treatment at the casualty clearing station, the surgeon is advised to use all possible care in suturing the torn skin and mucous membrane, so that raw ends of bones may be covered and skin and mucosa may be approximated at the margins of the wound; but all stitches must be inserted without tension. Submandibular drainage is advocated for injuries of the lower jaw, in view of the high incidence of abscess formation, and, to prevent adhesions obliterating the buccal sulci, the use of a piece of stout rubber tubing encircling the sulci is suggested. The dental surgeon is given two principles which should guide him in the early stages; one is that he should be as conservative as possible in dealing with loose fragments of bone and injured teeth; the second that he should attempt fixation of the fragments in accurate position. Interdental wiring is recommended, or, in the absence of teeth, splinting by means of unbroken dentures, or of gutta-percha moulded into the mouth. Anæsthesia is advised, since it is not thought likely that post-operative vomiting will give rise to suffocation where dental wiring has been used.

The committee believes "a special hospital reserved solely for the treatment of maxillo-facial injuries is preferable to special departments in general hospitals, provided that the number of cases justifies it." The treatment of these cases tends to be tedious, to extend over a long time, and to involve a succession of operations. The provision of an auxiliary hospital to which patients can be transferred in the intervals of active treatment is almost a necessity, but unity of control is essential. The plans for the special hospital have been based on those of Sidcup Hospital, designed as a maxillo-facial hospital during the late war, and it is felt that a suitable working unit is 200 beds, with a possible extension of the number to 500. On reaching the special hospital the patient is placed under the charge of the surgeon who is to carry out the final bone-grafting and plastic operations, but the coöperation of the dental surgeon is necessary from the outset, and, in cases not requiring plastic work, he may have complete control.

An appendix to the report contains the contrasting views of Mr. Warwick James and of Mr. Kelsey Fry on the relative values of interdental wiring and of metal-cap splinting in the fixation of fractures of the mandible and maxillæ. We have previously referred[2] to the arguments advanced by the adherents of the two methods. It is allowed that good results can be achieved by either procedure, though it can be argued that one or the other gives more certainty of success. The main points on which discussion centres are the rapidity with which satisfactory immobilisation can be effected; the amount of attention necessary afterwards (a vital consideration in the conditions of war); the possibility of keeping the mouth clean; and the prevention of interference by a non-coöperative patient. Although no conclusion was possible on the relative merits of wiring and splinting, the report gives a useful summary of the methods advised for fractures at particular sites and with various complications.

A RAPID SURVEY OF BIOLOGICAL PROBLEMS

THE form of a Platonic dialogue has been adopted in a stimulating general survey of biological problems which has recently appeared in a translation from the German.[3] A, the Socrates, is made to discourse for twenty-one successive evenings upon biological problems. B, the intelligent laymen thirsting for knowledge, hangs upon the lips of his teacher suggesting difficulties and asking questions, many of which the other is hard put to it to answer. Dr. Thesing has on the whole been extraordinarily successful in this method of presenting the subject—a method which in less skilful hands could easily become tedious. The field covered by the discussions is vast. From the origin of the world and of life we are brought into touch with most of the major problems confronting the various biological sciences. The origin of man, immunity, hormones, heredity, evolution, eugenics, ecology, and many other subjects are discussed in the light of modern research. Specialists in each subject could of course find several points of detail with which to disagree; on the whole these are not important, but in the section on development no mention is made of recent experimental work on the factors which determine the fate of cells in the embryo, and this constitutes a serious omission. It is refreshing after the dogmatism of many recent popular biological books to find a clear statement of the difficulties in the way of accepting in toto any one of the prevalent theories of evolution. The attitude adopted towards controversial questions is in fact singularly impartial, and it is interesting to note that this impartiality extends even to questions of racial biology.

THE COMMONWEALTH FUND

THE report of the Commonwealth Fund speaks modestly of its little gift (\$1,720,514·54) made to the British and American peoples during the year 1934. While others debate the burning issues of "medical economies" the Commonwealth Fund has concerned itself with attempting to raise the standards of medical service. One method of raising standards in rural communities is the establishment of the community hospital. Six rural hospitals have been sponsored by the fund as models of what a community hospital should be. All but one of the hospitals have shown increased occupancy in 1934 as compared with 1933 and their financial position is much stronger; earned cash receipts have gone up by 31 per cent., net indebtedness has been cut in half. An extensive demonstration of rural health work in Tennessee has had, as was intended, an educational value besides making a contribution to social welfare. Both in Mississipi and Massachusetts the Fund has aided in raising the standards of local health units; in the former State by sponsoring within the State health department travelling advisory and supervising units; in Massachusetts by promoting the formation of a model district health unit coördinating the efforts of sixteen towns in the south-western part of the State which previously had functioned as independent public health units. This demonstration should provide a much-needed lesson in the Eastern United States, for the old system of township units still has a devitalising grip upon public health administration even in such a progressive State as New York. In the Mountain State of New Mexico the Commonwealth Fund had for four years been helping to provide public health nurses in 15 out of the 31 counties. At the present time these nursing services, now established in the goodwill of the population, are deriving a large part of their support from local funds. To the north of New Mexico is Denver wherein is lodged the medical school of the University of Colorado. Here the Fund is supporting a significant study of normal child development. The study is being made of 100 Denver children and is under the general guidance of a pædiatrician. At suitable intervals, beginning a few weeks after birth, specially trained workers determine a record for each child: the most important bodily measurements; the development of the bones and muscles generally and posture; the development of the jaws and teeth (by plaster casts and X ray); the development of the head bones and sinuses and of the chest and heart (by X ray); the behaviour of the heart (by electrocardiograph); the basal metabolic rate; the mentality and general social adjustment. Each child is examined every quarter by a pædiatrician. Other studies are made in special groups of infants and children. The Child Research Council finds no lack of uncharted territory in the anatomy and physiology of the earlier years of human life.

Besides its medical and public health work the Fund provides fellowships to enable British university students "to spend two years as guests of the Fund in graduate study at American universities and in first-hand observation of American life." In the last ten years 260 such fellowships have been granted. Until his death last year Sir Walter Buchanan-Riddell was chairman of the committee of award; he has been succeeded by Sir Walter H. Moberly, whose academic associations put him in an excellent position to assess the claim of candidates. It is interesting that 40 per cent. of the returned fellows are now holding positions in British and Colonial schools, colleges, and universities.

AIR RAIDS AND POISON GAS

THE Home Office last week issued a circular[1] describing the precautionary measures to be taken for the protection of the public against attack by hostile aircraft. The Government feel they would be neglecting their duty to the civil population if they failed to take such precautions, since developments in the air have made it possible for attacks to be delivered—and delivered suddenly—on many parts of this country; but the circular states that "the need for these measures in no way implies a risk of war in the near future; nor does it imply any relaxation of effort on the part of His Majesty's Government to ensure the promotion and maintenance of peace by all the means in their power." The first step has been to establish an Air Raid Precautions Department at the Home Office and this will be directly responsible for central activities including the issue of warnings, the accumulation of gas respirators and protective clothing for certain air-raid services, the coördination of demands for hospital equipment, the storage of bleaching-powder for decontamination of gassed areas, and the issue of advice. The British Red Cross Society and the Order of St. John of Jerusalem are also to play their part, by the enrolment and training of emergency personnel, especially for medical and anti-gas services, and in the instruction of the public. The main responsibility, however, is to rest with the local authorities, which must arrange schemes for treatment of casualties, and the maintenance of all the essential services in their charge. These are briefly outlined in the circular, but fuller information for the authorities and the public will be given in a series of handbooks to be issued in due course. Meanwhile those interested in the subject can easily find other sources of information, both reassuring and otherwise. In the first category we have Mr. Davidson Pratt's recent lecture to the British Science Guild[2]; he thinks that the terrors of gas attacks have been much exaggerated, and believes that the civil population as a whole, if trained against panic, will find tolerable safety by staying in gas-proofed rooms in their own houses. The Union of Democratic Control, on the other hand, after reviewing[3] the incendiary and toxic agents available, quotes the conclusion of a commission of the International Red Cross (1928) that if the technique of offensive weapons continues to improve "the fatal moment must arrive in which the question of defence, already extremely difficult in view of the means already available, becomes an insoluble problem. A large proportion of the inhabitants of populated towns must be doomed to destruction." In these circumstances, it is suggested, the precautions proposed by Mr. Davidson Pratt and others cannot be taken at their face value, and the public should be fully informed of the facts, as summarised in the Union's pamphlet. By way of alternative, more technical details are obtainable, if desired, from the official "Manual of the Medical Aspects of Chemical Warfare" (1926) or, with later details, in a paper just issued by Dr. Bischoff[4] of Lugano, who describes the symptoms, signs, and treatment of various forms of gas-poisoning. Evidently the medical profession will soon be expected to enlarge its repertoire so as to be able to deal with these new man-made diseases. But like other pathological conditions they are more easily prevented (one would suppose) than cured.

THE EMPLOYMENT OF MARRIED MEDICAL WOMEN

THE general purposes committee of the L.C.C. have been considering representations received from various organisations with reference to the employment of married women; the object of the representations has been to secure that married women should be eligible for employment without restriction throughout the Council's service. The committee report that they have considered the question from the point of view of the public service and not in the interest of any category of the staff and have come to the conclusion that in two instances, those of the medical and teaching professions, material advantage to the public service would result if married women were eligible for service as officers of the Council. Their main reasons are that the duties of both doctor and teacher call for certain personal qualities which may be thought to be enriched by marriage, and that the training of women entering these professions involves in many cases considerable expenditure of public money, the fruits of which are lost to the community if the career of every woman is terminated by marriage. They propose, therefore, subject to certain limitations, that the restrictions which at present debar married women in these professions from entering or remaining in the Council's service should be withdrawn. As far as medical women are concerned the new proposal will apply to full-time doctors, except in the hospital and institutional medical and mental hospital service, and to non-resident part-time and sessional doctors. The holders of resident appointments are excluded from the new proposals because it is inherent in the nature of such appointments that their holders should be available for duty when required at any hour of the day or night, and the committee feel that the demands thus imposed are incompatible with the normal domestic and family responsibilities of a married woman. There is, moreover, the immediate practical difficulty of a lack of married quarters. In the event of pregnancy medical women as well as teachers will be required to take 17 weeks' compulsory confinement leave on half pay, of which 4 weeks is to be taken before and 13 after the confinement (4 weeks if the child does not live). Payment for the last 8 weeks of this period is to be withheld until the teacher or medical woman has been back at work for 3 months. The adoption of these proposals, which were accepted by the London County Council on July 16th, will involve some adjustments in superannuation provisions and certain exceptions in respect of officers transferred from the Local Government Board who were engaged under different conditions of service. The concessions are in the nature of a compromise which will give complete satisfaction neither to diehards nor to feminists. The former will continue to protest that however much skill, training, and experience a professional woman may have, her service should be lost to the community on her marriage; the organisations who made representations to the Council will be disappointed that, though its practice has been altered in respect of certain classes of certain professions, the Council has not accepted the principle underlying their representations. For ourselves, we hold that the step just taken is in the right direction and have little doubt that its success will warrant an extension in London and elsewhere of the groups of women allowed to retain their posts after marriage.

JUVENILE RHEUMATISM IN INDIA

To the controversy on whether rheumatic fever occurs in the tropics, Dr. K. L. Wig[1] contributes a record of 30 cases of rheumatic infection in childhood collected in the out-patient department of the Mayo Hospital, Lahore. At a time when the subject was under discussion his interest was aroused by an obvious example of juvenile rheumatism in a boy of ten who developed high fever, swollen joints, subcutaneous nodules, and carditis; salicylates controlled the arthritic phase, but the carditis seems to have been progressive and fatal. Of the 30 patients with evidence of juvenile rheumatism seen at the Mayo Hospital since the beginning of last year, 10 have had simple articular rheumatism (usually subacute) and the brief summaries given, with descriptions of recurrent sore-throat and joint involvement, leave no doubt of the nature of the malady. The same applies to the other two groups—i.e., 5 children with chorea, 4 of whom had a history of joint pains, and 15 patients with involvement of the heart. Some of the latter were adults with established mitral stenosis, with or without auricular fibrillation; the younger ones had early signs of valvular disease. Three young adults, aged 22, 24, and 25, had aortic regurgitation with mitral stenosis, following a definite history of rheumatic arthritis; and this is important since some observers have claimed that, while syphilitic aortic disease is common, rheumatic carditis is rare in the Punjab. The patients in the present series came from villages as well as from congested areas of the towns. Most of them were poor, but that may be because the hospital out-patient population is mostly poor. The rheumatic nature of the illnesses cannot be doubted and it is noticeable that usually, as in this country, the joints were involved at early ages.

AT a meeting of the council of the Royal College of Surgeons of England on July 11th Sir Cuthbert Wallace was elected president.

THE resignation is announced of Miss Ruth Darbyshire, R.R.C., after a serious illness, from the post of matron of University College Hospital. Miss Darbyshire was one of the two matrons who sat on the Lancet Commission on Nursing (1930–32) and deeply impressed her colleagues by her breadth of view, candour, and anxiety to modernise the conditions of hospital service while retaining its fine traditions. At the end of 1932 she was elected a member of the General Nursing Council for England and Wales, and in January of this year she was made vice-chairman of the Council. Her retirement from hospital work is less to be regretted inasmuch as it will give her more leisure in the future for her activities on behalf of a rapidly developing profession.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXI.—PROGNOSIS IN EPIDEMIC ENCEPHALITIS: ACUTE AND CHRONIC

IN most epidemic diseases prognosis is chiefly concerned in answering the question, "Will the patient live through the acute illness?" In epidemic encephalitis it goes much further. Even if the acute stage is survived without apparent damage, there is always the possibility of later developments which may not show themselves until long afterwards. When they do, prognosis is required, not only as to the duration of life but as to the temporary or permanent nature of the disorder, and in the latter case as to whether it will remain stationary or become progressively worse. Many of these questions it is as yet only possible to answer in part.

Prognosis in the Acute Stage

AS REGARDS LIFE

There are many possible sources of error in the data on which all case-mortalities are based, owing to the frequent absence of any clear-cut beginning or end of the acute stage, the occasional impossibility of recognising the true nature of even a serious attack, the frequency of unrecognised abortive attacks, and the fact that the number of "occult" cases—i.e., unrecognisable infections without symptoms—is difficult even to guess at. A. S. MacNalty (Epidemic Diseases of the Central Nervous System. London, 1927, p. 151), from the notification figures (1919–1923) found the case-mortality in England and Wales to be 54 per cent. In the Sheffield outbreak of 1924 it came to considerably less. Out of the 301 acute cases notified during the year only 43 died in the acute attack (14·3 per cent.). Similar discrepancies are found in individual records elsewhere. Taking all things into consideration, it would seem that a case-mortality of somewhere about 25 or 30 per cent. is a reasonable figure.

It is generally agreed that the acute attack is more often fatal at later periods of life than in younger persons. It is said by some that the prognosis is also more grave in infancy. In the Sheffield epidemic of 1924 the mortality was high in cases with early respiratory symptoms (polypnœa) but low in cases with abdominal myoclonus as the chief symptom. In a large series of attacks occurring in pregnancy F. Roques (1928) found a case-mortality of 42 per cent. The mortality figures for infection during pregnancy, however, differ somewhat widely. On the whole, to make a prognosis as to life in the acute stage is of little value until symptoms of grave omen or definite signs of convalescence have set in. Cases which for some days are apparently mild may, suddenly, become gravely worse, and even after apparent convalescence fatal symptoms may supervene.

The expectation of after-effects.—Here, also, data are scanty and difficult to obtain. The long period of apparent health, in some cases extending to several years, which may intervene between the recognised acute attack and the onset of chronic symptoms, makes the follow-up of many cases exceedingly difficult. At the end of 1925 a careful follow-up of the 300 acute cases in the Sheffield outbreak (spring, 1924) showed that only about 18 per cent. had recovered completely.

In most of the cases recorded as complete recoveries the original attack had been of mild type. On the other hand, parkinsonism, even of a severe kind, may follow not only a mild acute illness or an abortive attack, but even an "occult" infection. It would also seem to be comparatively rare for complete recovery to follow a severe primary attack. As to the exact form which the after-effects of a severe attack may take, there are no data on which to form a prognosis.

PROGNOSIS IN THE CHRONIC STAGES

As this includes many conditions in which the prognosis is different, it will be more convenient to consider each separately.

(a) *Disorders of sleep.*—In most cases these disappear largely if not wholly within a year or two of the acute attack, whether treated or not. Although in particular individuals sleep may remain abnormal for years, on the whole the permanent amount of this disorder is not a marked feature.

(b) *Various spasmodic attacks.*—The prognosis as regards polypnœa, jaw attacks, torsion spasms, and so forth is much the same as that relating to sleep disturbance. Even severe attacks of torsion spasm, occurring frequently, may after a few months or years become less and eventually disappear.

(c) *Polyuria* is not a common complication. In one severe case in my experience it cleared up completely after lasting for about a year. The man eventually developed severe parkinsonism.

(d) *Epileptic fits.*—Both major and minor fits may occur for the first time either in the acute or chronic stage. Their presence does not necessarily add to the gravity of prognosis. They do not tend to increase in number or severity.

(e) *Mental and moral changes.*—Some of those who during or soon after the acute attack become dangerously impulsive or actively suicidal may improve in those respects in course of time. Such improvement, however, is often associated with an increase in parkinsonism. G. A. Borthwick (Encephalitis Lethargica. London County Council's Report, 1931, No. 2811) at Winchmore Hill finds that of the children showing behaviouristic disorders "the milder cases have done well with the orderly routine of the hospital, and whilst in residence have almost reached normal standards of behaviour." In the more severe cases, however, the prognosis is bad and real improvement is not to be anticipated.

(f) *Oculo-gyric attacks.*—These are always associated with definite, although in some cases only slight, signs of parkinsonism. In a few cases they may, from time to time, become either less frequent or less severe, or both. In one or two this has seemed to be the result of treatment, but detailed inquiry has failed to prove any definite causal relationship. The prognosis as to these is that they continue to occur, at any rate, for ten years after onset.

Post-encephalitic Parkinsonism

DURATION OF LIFE

The parkinsonian syndrome alone does not necessarily shorten life. It must, however, be borne in mind that many of the parkinsonians affected as the result of epidemic encephalitis have received much wider damage to the central nervous system than that which brings about this syndrome alone.

Up to the end of 1934 it has been possible to follow up completely 289 out of over 500 cases of post-encephalitic parkinsonism, of which we have records

Of these 289, 77 have died (just over one-quarter), so that nearly three-quarters of these parkinsonians are alive, at least ten years from the date of the acute infection—and some as much as 15 or 16 years. (In our series the number of acute infections dating from later than 1924 is so small as to be negligible.)

The 77 fatal cases may be divided into two groups: (*a*) those in whom death was not directly due to the disease; (*b*) those in whom death was probably directly due to the disease.

(A) *Death not directly due to the disease.*—24 cases (M., 16; F., 8).

(1) Suicide: 7 cases (M., 5; F., 2).

(2) Accidents: 5 cases (M., 3; F., 2). Three of these were due to bradykinesia. The two women fell on the fire and were fatally burned; one man was found face down in a shallow pool of water. There was no question of suicide in any of these.

(3) Intercurrent diseases: 12 cases (M., 8; F., 4).

(B) *Death probably directly due to the disease.*—53 cases (M., 26; F., 27).

(1) Gradual progressive decline: 45 cases (M., 23; F., 22). It has not been possible to obtain the exact mode of death in many of these cases, but most of them were more or less bedridden, and some had been so for long—sometimes with extreme emaciation and bedsores. Possibly in many some terminal infection ended the scene. The duration of these varied widely: 31 died within five years of infection; 10 died between five and ten years after infection; 4 died more than ten years after infection. The longest was 17 years after. This was a man whose acute attack occurred with the Army in France, in 1917.

(2) Sudden unexpected death: 9 cases (M., 3; F., 6).

These occurred in two ways: (*a*) In seven, death occurred whilst in bed, sometime in the early morning. Six of these were young women and one a youth. In all these the possibility of suicide or of accidental smothering may be certainly excluded. Involvement of the respiratory centre seems a possible explanation. (*b*) In the two remaining cases of sudden death—both males—the cause was a sudden hyperpyrexia with no other symptoms. In each of these death occurred within 24 hours of onset. In one the man had been under close observation in a mental hospital for several years, and except for a parkinsonism of hemiplegic type, was apparently very well. His temperature reached 109° before death. Involvement of the temperature centres seems a possible explanation.

None of these cases of sudden death were bedridden at the time of death, indeed, most of them were able to go about actively; nor was any particular intensive treatment being carried out.

PROGRESS OF DISEASE

As was mentioned above, almost 75 per cent. cases of parkinsonism may be expected to live for at least 10 or 15 years. How much longer remains to be seen. The question then arises: What is their condition likely to be during that period? To form an idea of this we have divided our cases into three groups according to their capacity for looking after themselves—i.e., as regards dressing, feeding, walking about, &c.: group I., completely independent; group II., partially dependent; group III., completely dependent.

A follow-up of 212 cases living at the end of at least ten years from the date of acute infection gives the following: group I., 70 per cent.; group II., 18·5 per cent.; group III., 11·5 per cent.

These cases include a certain number in institutions and also those attending the out-patient clinic.

CONCLUSIONS AS REGARDS CHRONIC PARKINSONISM.

1. Absolute recovery with complete disappearance of all symptoms is unknown.

2. Complete or almost complete standstill does occur, at any rate, for as much as 16 years.

3. Most cases tend to become worse, but the rate at which this happens is extremely variable. In a few it may be measured by weeks, in more by months, in most by years.

4. Suitable treatment may cause marked improvement in the muscular rigidity and, if continued, maintain the improvement for long periods.

5. Tremor, when once developed, does not disappear entirely, but tends to get worse. No treatment yet known has any permanent effect in stopping it.

6. Excluding suicide and accident, about 23 per cent. of parkinsonians die within 10 or 15 years of infection. Of these, in about 15 per cent. the end is expected, and preceded by progressive failure; in about 5 per cent. there is definite intercurrent disease; whilst in about 3 per cent. sudden and unexpected death may occur at any time whilst the patient is apparently in his usual health.

ARTHUR J. HALL, M.D., F.R.C.P.,
Emeritus Professor of Medicine, University of Sheffield;
Consulting Physician to the Sheffield Royal Hospital
and in charge of Encephalitis Clinic; Visiting
Physician, S. Yorks Mental Hospital and
State Institution, Rampton.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

Surg. Comdr. W. J. Morris to *Victory* for R.N.V.

Surg. Lts. L. G. Yendoll to *Vernon*, J. M. T. Reese to *Codrington*, and J. L. S. Coulter to *Maine*.

Surg. Lt. (D.) S. R. Wallis to *Ramillies*.

Proby. Surg. Sub.-Lt. R. F. Hand to *Lucia*.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt.-Comdrs. S. B. Borthwick to *Pembroke* for R.N.B. and to *Australia*, A. S. Bradlaw to *Courageous*, and H. A. M. Whitby to *Rodney*

ROYAL AIR FORCE

Flight Lt. R. K. Muir to No. 3 Armament Training Camp, Sutton Bridge.

Wing Comdr. T. C. St. C. Morton to R.A.F. Institute of Pathology and Tropical Medicine, Halton, for duty as Commanding Officer.

Flight Lt. O. M. Fraser to R.A.F. Hospital, Cranwell.

Dental Branch.—Flight Lts. J. M. Jamie and F. B. Sumerling are transferred to the Reserve, class D. Flying Offr. K. G. Swiss, to Medical Training Depôt, Halton, on appointment to a non-permanent commission.

AUXILIARY AIR FORCE

No. 603 (City of Edinburgh) (Bomber) Squadron: I. A. G. L. Dick is granted a commn. as Flying Offr.

INDIAN MEDICAL SERVICE

The undermentioned apptmts. are made:—

Majs. to be Lt.-Cols.: C. J. L. Patch, M.C., and S. L. Mitra.

To be Lts. (on prob.).: Raymund Joseph Henderson and C. W. A. Searle.

Indian Medical Department.—Maj. (Sen. Asst. Surg.) A. R. H. Boyne retires.

COLONIAL MEDICAL SERVICE

Dr. H. B. Boucher has been appointed Medical Officer, Nigeria.

THE BEST METHOD OF MANUAL ARTIFICIAL RESPIRATION AND HOW TO APPLY IT

By C. J. Mijnlieff, M.D.

SECRETARY-GENERAL OF THE INTERNATIONAL SOCIETY FOR LIFE-SAVING AND FIRST AID IN ACCIDENTS, AMSTERDAM

> ". . . The negative result of a search of the literature has made me conclude that the mechanical side of respiration has not received the attention it deserves."
> —*Sir Charlton Briscoe* (1927)

Scientific investigations have led us to change our views of the requirements which a method of artificial respiration must meet. These may be summarised as follows.

THE DESIDERATA

1. *Sufficient ventilation of the lungs must be secured.*—In experiments on living persons (or animals) and on cadavers several factors have to be taken into consideration: in living persons, their unconscious and involuntary breathing, the muscular tonus of the muscles and the reflexes; in the cadaver, the altered tonus and rigor mortis. Because of failure to give these factors their proper weight the conclusions drawn from many experiments are not of great value. Thus the results of all investigations before Ploman's must be judged with reserve, and also those of Schäfer and Hamburger. Values before Liljestrand are wrong; but his own observations were very useful, and he took also into account the influence of frequency of respiration (see Table).

Ventilation of the Lung by various methods of Artificial Respiration, According to Various Investigators

Investigation by—	Method of—	No. of resp. per min.	Ventilation— Per resp. (litres).	Ventilation— Per min. (litres).
Ploman (1906) ..	Silvester ..	7–12	1·2–2·0	12–20
	Howard ..	10–14	1·0	10–15
	Schäfer ..	16–20	0·5–0·6	8–12
Liljestrand (1913).	Silvester ..	15	0·54	8·1
	Schäfer ..	15	0·50	7·5
During apnœa ..	Silvester ..	15	0·19	2·85
	Schäfer ..	15	0·17	2·55
Loewy-Meyer (1919)	Howard ..	14	0·447	6.25
	Silvester-Brosch	9–10	1·121	10·65
Bruns (1923) ..	Silvester ..	—	0·2	—
	Howard ..	—	0·05	—
	Van Hasselt-Schüller ..	—	0·1	—
	Schäfer ..	—	0·02	—

In looking at this Table it must be borne in mind that Ploman, Liljestrand, and Loewy-Meyer experimented on living persons, Bruns on the still warm cadaver. The figures in the experiments on persons in a state of apnœa are really too low because the tonus of muscles, especially of the diaphragm, is increased in apnœa (Loewy). Bruns's figures are also probably too low, because a certain amount of rigor mortis had set in. Hence the absolute values obtained cannot be regarded as reliable; but the figures are nevertheless important because they give an idea of the comparative value of the various methods employed. It will be seen that quantitatively Silvester's method gives the best ventilation.

2. *Absorption of oxygen and excretion of carbon dioxide in the alveoli, and respiratory blood circulation to and from the heart, must be promoted.*—What Brosch said in his criticism of expiratory methods is very true: "The human and animal organism does not need a physical inspiration (entrance of air into the bronchial tree) but a physiological inspiration (entrance of air into the alveoli)." Ploman and Brosch inferred that methods promoting active inspiration as well as active expiration are to be preferred because they introduce more air, cause greater enlargement of the thorax and increase the pulmonary circulation of blood. We now know that this last action is of great importance in the treatment of apparent death and that it can be secured only by rhythmical increase and decrease of the negative pressure in the thorax, as in physiological breathing; the walls of the alveoli are distended, capillaries in these walls are relaxed and dilated and blood thereupon flows from the right to the left side of the heart.

3. *The nutrition and function of the heart itself, and as far as possible of the large somatic circulation, must be promoted.*—Bruns has determined the effect of different methods of artificial respiration on blood pressure, which he measured in the cadaver at various places in the heart, large arteries and veins. Under Silvester's classical method the pressure dropped 8 cm. (of water) on inspiration and rose 1 cm. on expiration; under Silvester's method with expiratory pressure on the thorax it also dropped 8 cm. on inspiration, but rose 18 cm. on expiration; under Howard's method it dropped only 0·5 cm. on inspiration and rose 10 cm. on expiration. But with Schäfer's method, directly the cadaver was turned over the manometer registered a *positive* pressure of 12 cm., and despite strong expiratory pressure upon it there were no variations of any importance. This means that in Schäfer's method no inspiratory or expiratory change in the blood pressure is brought about; hence it has no influence on the circulation of blood. Silvester's, on the other hand, has a very favourable influence on the passage of blood—also much greater than Howard's.

Bruns showed that in the cadaver artificial respiration by Silvester's method caused blood to pass from the right side of the heart to the middle branches of the basilar artery in eight minutes. He has also shown that Silvester's plus Howard's method arterialised the blood in both sides of the heart very considerably; thus in twenty minutes its oxygen content rose from 8 per cent. to 24 per cent. and by inhalation of oxygen to 48 per cent. Bruns and Thiel have proved, moreover, that the method causes blood to flow into the finest branches of the coronary arteries. And here it is appropriate to recall Magnus's observation that after oxygen has ceased to reach it the heart contains for four or five minutes a reserve of oxygen. Furthermore, when the heart is stopped reflexly, the lungs, blood, and tissues may still contain enough oxygen to preserve the irritability of the heart as long as twenty minutes.

Many investigators have made it clear that artificial respiration in itself has a favourable influence on the heart's action and that Silvester's method stimulates the heart probably as follows: mechanically, by pressure on the thorax, rhythmically repeated, causing, by the resulting alternate diminution and enlargement of the thorax, a pulling of the various parts of the heart (especially the auricles) and of the large vessels at their origins; and by rhythmical alteration of the contents of the heart and large blood-vessels. It also acts reflexly—by enlarging and diminishing the chest cavity, distending the lungs, making the pleuræ tense, and stretching the diaphragm—through the vagus and phrenic nerves.

Bruns (1934) has now proved, by experiments on dogs, that after the heart has been stopped (ascertained by clinical examination) by asphyxia, action currents in its muscle can still be demonstrated during some half hours. Also that at this time *normal lasting* heart action and respiration can still be evoked by Silvester's or Howard's method together with indirect massage of the heart, not by artificial respiration alone.

It seems to me that on these considerations Schäfer's method can hardly be recommended. The above experiments suggest that Silvester's modified method is the best means of meeting requirements 2 and 3.

4. Last, but not least, *there must, as far as possible, be no injury to the patient.*—It has been said that Silvester's method carries a danger of fracture of the ribs; but such an accident is possible only if it is carried out very roughly. Not long ago I inquired of every pathological institute in the Netherlands and found no case reported for 30 years or more, although Silvester's is the method far and away the most often used. In Howard's method the danger is greater.

Schäfer wrote of the risk of rupture of the liver if Silvester's method is used; but in my inquiry no such case was discovered and I agree with Keith that this risk is much greater with Schäfer's own method. Nevertheless this danger should be borne in mind, and also the possibility of rupturing the thin-walled right side of the heart distended with blood.

One advantage of Schäfer's method is said to be that when the patient is lying face downwards, water, mucus, and dirt can flow out of his mouth. I regard this rather as a danger than an advantage; for every time we lean on the small of the patient's back the stomach may be compressed and some of its contents (mud, bits of fruit, &c.) may be pressed suddenly or gradually upwards above the level of the vocal cords, so that the next inspiration sucks them deep into the trachea. Not long ago a case well known in forensic medicine in Holland proved that this danger is no imaginary one (although in this instance Howard's method was employed).

My examination of current methods of artificial respiration has thus led me to disapprove of Schäfer's method, notwithstanding its simplicity, and to affirm that Silvester's—as modified by the facts discovered since he introduced it—is the best.

HOW DOES SILVESTER'S METHOD WORK?

An anatomical investigation made in Prof. M. W. Woerdeman's department at Amsterdam has brought me to certain definite conclusions about the best way of applying Silvester's method. When I had finished my research, my attention was drawn to Sir Charlton Briscoe's Lumleian lectures on physiological respiration; and his words reproduced at the head of this paper agree with my own conclusion.

Hitherto all investigators have taken it for granted that, in Silvester's method, the chest expands through the extension of the muscles—especially the chest muscles—caused by the upward, backward, and downward movements of the arms. On this assumption Silvester advised—and so far he has been followed by every other investigator—vigorous traction of the arms. I shall now show that this is a mistake.

After the muscles of a cadaver from the head to the pelvis have been prepared, and the sternum sawn through or not, Silvester's method can be demonstrated perfectly by moving the arms when the pectoralis major and minor, latissimus dorsi, &c., have been severed. Its action is just the same as when the muscles are intact, and from this it is obvious that these muscles cannot be of any importance for artificial respiration. They only become tense when for other reasons movements of the scapulæ, clavicles, sternum, and ribs have been made. And in the apparently dead person the muscle-fibres are too weak, and the fasciæ (at least those of the large chest muscles) too thin, to offer much resistance to the forcible movements of artificial respiration.

Let us see what happens when Silvester's method is applied.

If the patient is lying horizontally, movements of the arm upwards, backwards, and downwards involve the shoulder-joint only until the arms are at right angles to the body, or less; after the lowest part of the shoulder capsule has stretched to its fullest extent any further movement of the arms backwards and downwards is carried out in the shoulder-ring. If the humerus is not abducted too much—and excessive abduction should be avoided because it presses the humerus against the acromion process and starts a false movement of the scapula—the humerus will push against the elastic roof of the shoulder-joint, formed by the acromion, the coraco-acromial ligament and the coracoid. Above this roof runs the clavicle, which is connected with the scapula by the acromioclavicular joint and (above the coracoid) by the strong coracoclavicular ligament, with the first rib by the costoclavicular ligament and the subclavius muscle, and with the sternum by the sternoclavicular joint and the strong sternoclavicular ligament.

The anterior chest muscles do not become tense, and the coracoid does not move backwards, until the arm is at right angles. But when the coracoid has been turned upwards and backwards, so making the pectoralis minor tense, the movements next described have already started. Further movements of the arms backwards and downwards are made possible, and at the same time limited by the mobility of the scapula and the clavicle round an axis which joins the sternal end of the clavicle to the inferior angle of the scapula. The scapula turns by the strong tension in the coraco-acromial and coraco-clavicular ligaments, in such a way that its lowest point deviates laterally 9–11 cm. from its normal position (up to 19 cm. from the vertical column) being fixed, as it were, in position and pressed against the thorax by a common muscle plate formed by the rhomboid, serratus anticus, and latissimus dorsi muscles (Mollier). (See Figure.)

During these movements of the arms backwards and downwards the humerus presses first against the clavicle, which then rotates, forwards and upwards round its own axis, at the sternoclavicular joint. This rotation, owing to the joint connexion with the sternum and to the strong costoclavicular ligament (+ subclavius muscle), causes the sternum and the first rib, and subsequently also the other ribs by the intercostal ligaments (and muscles), to make the movements characteristic of ordinary maximal inspiration. The pectoralis major is of practically no importance here; the pectoralis minor, by reason of its thicker and tougher tendons, may play some part. At the end of the movements the lowest ribs are drawn up and the latissimus dorsi is stretched.

When the ribs have been rotated to the maximum extent permitted by the costovertebral joints, the costovertebral ligaments and particularly the costo-transverse ligaments are so much stretched that the spine is first extended and then takes up a position of lordosis. This extended position is the one most favourable for artificial respiration, for the thoracic cavity is then enlarged as much as possible in all dimensions—longitudinal, transverse, and sagittal. By moderate extension of the spine the abdominal cavity is enlarged, and this relieves the diaphragm from the pressure on its underside of the liver and other abdominal contents and brings it into a better position for inspiration. In the position of lordosis, on the other hand, the abdominal wall is brought nearer the vertebral column, the superficial abdominal fascia becomes more and more stretched, the xiphoid process is pressed back, and the lower ribs are hampered in their movement upwards by the increased tension of the side walls of the abdomen (Strasser); the chest is more or less flattened and the thoracic cavity therefore decreased. Moreover, when the lordosis is carried further the pelvis is lifted up and this throws the abdominal contents against the diaphragm, thus making the thoracic cavity still smaller. Hence I do not think it advisable to continue extension farther than the straightening of the thoracic vertebral column which follows automatically the arm movements indicated above, provided that a *thick* folded coat or blanket has been placed under the back.

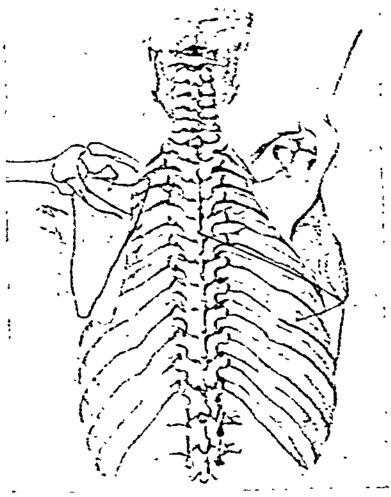

Diagram illustrating abduction and elevation of the arms. (Reproduced from H. Braus, "Anatomie des Menschen," Berlin, 1921.)

HOW TO PERFORM ARTIFICIAL RESPIRATION

For the above reasons I advise the application of Silvester's method as follows.

The mouth and throat are first cleared of water, mucus, mud, artificial teeth, or food debris. The clothes are then loosened and the patient turned on his back. A thin folded coat or blanket may be placed under the back, from the neck to the loins, to steady the patient and allow free movement of the shoulder blades. The lower jaw is pressed forward and the head turned well to one side, bending it back so that the neck is stretched, in order to keep the entrance to the air passage free. The tongue can be held out with forceps (according to Leyden) or bound with a small lace or tape outside the teeth, tying the ends together at the back of the neck.

The method should begin with an *inspiratory* manipulation, expanding the chest and consequently increasing the negative pressure, to relieve the task of the right side of the heart, probably overfilled with blood. The operator kneels on one knee—a position less tiring than any other—and grasps the arms with his thumbs in the bend of the elbow and his fingers enclosing its point. When he moves the arms upwards, backwards, and downwards so that the humerus comes into contact with the coraco-acromial ligament, the thumbs turn round the elbows; and when he presses the elbows back alongside the head the thumbs come to lie on the outside of the elbows. This pressure should be firm, and will then, lead to the maximum enlargement of the thorax; the spine will be straightened but the abdominal wall will not be too tense. The patient is left in this position for a second, to allow air to penetrate into the lungs, and then the arms are returned along the same path, upwards, forwards, and downwards, and the elbows are pressed together carefully. This considerably narrows the thorax by shortening the sagittal diameter, without endangering the heart and liver, avoiding at the same time the danger of œdema of the lungs (Jellinek).

The question now arises: What should be the rate? From the investigations of Liljestrand, Bruns, and Rhaesa we know that with a frequency of 17 times a minute every respiration is used to its full value. In order to stimulate the heart a frequency as great as possible would be desirable; on the other hand, it is essential that the inspired air should mix with the air in the lungs. Accordingly I suggest that the correct rate is 15 artificial respirations per minute.

From the description I have given it may appear that an assistant is not strictly necessary, but the latest investigations of Bruns (1934) show that if possible, the heart should be stimulated by massage (70 to 100 times per minute) while artificial respiration is proceeding. Other assistants can rub the body with warm cloths and apply friction to the hands and feet. Oxygen should be administered if it is available, and if a doctor is present he should inject Coramine into a vein or even into the heart. If the heart functions again but respiration remains in abeyance, or if the heart is functioning from the beginning though the patient does not breathe, then artificial respiration must be continued, combined if possible with inhalation of oxygen mixed with 5–7 per cent. carbon dioxide. An injection of lobeline may be given to stimulate the respiratory centre.

Should there be a fracture of one or both arms, Silvester's method cannot be applied and Pacini's (which now, for the first time, in my opinion, can be properly understood), should be considered. This, however, may be too difficult for first-aid men. Therefore I should prefer van Hasselt-Schüller's method or a combination of van Hasselt's and Howard's. I do not agree with Ploman and others that Silvester's method can only be applied to muscular patients, for my anatomical research has shown that its action depends mainly on the joint capsules, strengthening bands and ligaments, and not on the muscles.

NATIONAL CONFERENCE ON MATERNITY AND CHILD WELFARE

(Concluded from p. 40)

THE health of the child between the ages of two and five years was further discussed at sessions of the Conference held on July 2nd and 3rd at Queen Mary Hall, Great Russell-street. Quoting Freud's statement that "the little human being is frequently a finished product in his fourth or fifth year," Prof. OLIVE WHEELER, D.Sc. (University College of South Wales and Monmouthshire, Cardiff), suggested that even before school age a child was capable of all the elementary thought processes found in more complicated forms in adults. She maintained further that the emotional growth of the individual in these early years was even more significant for the future, and that patterns of character and behaviour laid down at that time remained throughout life.

The Duchess of ATHOLL, M.P. (chairman), questioned this view on the ground that, carried to its logical conclusion, it would mean that subsequent training and self-discipline were doomed to failure. She took exception to an analogy between plant life and child life, the fundamental difference lying in the fact that the human being had a moral and spiritual nature which she believed was capable of overcoming the effects of even the worst beginnings.

Dr. WILLIAM MOODIE (director, London Child Guidance clinic) at another session upheld the opinion that certain tendencies and attitudes laid down before the age of five persisted right through life and that, though they might be overgrown, they were never destroyed, and might reappear at any time under stress. The habit of crawling, for example, was left behind with babyhood, but many people, faced with the ordeal of passing over a narrow and precipitous ledge, would instinctively drop on their hands and knees for greater safety. Dr. Moodie's experience led him to the conclusion that the public, especially parents, were inclined to exaggerate greatly the effects of trauma as a direct cause of breakdown, instead of recognising it as a danger signal pointing to the presence of underlying instability. He had known children pass through devastating experiences—being sexually assaulted, killing people accidentally, being present at the murder of their parents—and come through quite unscathed. Again, the breaking up of a home was not in itself of great importance; what mattered was the way in which it was broken, and the atmosphere of disturbance, recrimination, and half-truths that had preceded the rupture. The child or adult who broke down had been sensitised to shock beforehand by a long series of strains or stresses. Dr. Moodie had never met a child suffering from the result of psychological trauma pure and simple, though it was common enough to find children suffering from an anxiety state conveyed from a grown-up person by a continued process.

Mr. G. R. GIRDLESTONE (hon. surgeon and clinical director, *Wingfield-Morris orthopædic hospital*) mentioned four groups of conditions leading to physical disability: (1) congenital defects; (2) static or postural defects; (3) such conditions as tuberculosis of bones and joints, acute osteitis, arthritis, and poliomyelitis; and (4) injuries to any part of the locomotor system. The coöperation of many individuals—midwives, mothers, general practitioners, school medical officers, teachers, the staffs of general and cottage hospitals—was essential to ensure that these various types of case should find their way to the orthopædic hospital at the earliest possible moment. Mr. Girdlestone spoke enthusiastically of the successful treatment of acute anterior poliomyelitis by the administration of convalescent serum. Every child with an illness of the influenza type should be made to kiss his knees morning and evening. The moment he was unable to do so, owing to stiffness of the back or neck due to inflammation of the meninges, the case should be reported to the doctor for exact diagnosis and treatment.

Dr. ETHEL CASSIE (senior assistant medical officer of health for maternity and child welfare, Birmingham), who had investigated statistics of school entrants in Birmingham requiring medical treatment, emphasised the importance of infective conditions among young children. Although these ailments were less numerically impressive than non-infective conditions, they had far-reaching effects on health, happiness, and education. From the point of view of permanent or prolonged disability, tuberculosis, pulmonary infections, mastoid disease, and rheumatism stood high. Home visiting helped in the discovery of children suffering from these defects, and medical inspection made the diagnoses clear, but the real need was for early and prolonged treatment. All medical officers knew the child who had had pneumonia "three times," in other words, who had not recovered from one attack before breaking down again. Such children required long periods of convalescence in good surroundings, until the lungs were clear not only clinically but radiographically. Rheumatic infection also called for prolonged treatment, and the same was true of chronic otorrhœa and sinus infections.

Mr. C. PEYTON BALY, L.D.S., said that the school

dental service (though too often refused by parents) had done a good deal to improve the teeth of school leavers, but the teeth of entrants were still in a lamentable condition. Many authorities failed to make the best use of their dentists, the service being judged by the number of operations performed rather than by the condition of the children. Too much of the dentist's time was taken up by clerical work and treatment of casuals, allowing no time for instruction of teachers, children, and parents. The most valuable aids to sound teeth were clean fresh foods, especially milk and fruits, sunlight and air free from smoke pollution, cleaner habits, and more dentists to care for the mouths of mothers and children.

Dr. A. Doyne Bell (chief assistant, children's department, St. Thomas's Hospital) pointed out that the time between two and five years of age was the period of the child's maximum susceptibility to infectious disease, and at the same time he was coming increasingly in contact with infections owing to his developing gregariousness and growing ability to get about. Other factors contributing to the high incidence of infectious disease at this age were faulty nutrition and insufficient sleep, the latter being bound up with the problem of overcrowding. The object of studying dietetics was not to produce a child of standard weight and height but a healthy child. The financial problem of feeding a family could not be divorced from the dietetic problem. It was often an economic necessity to feed the young child on the same food as his parents, but this necessity could be turned into a virtue by teaching the parents to eat wholesome, well-cooked food. There was a tendency to discriminate too little between infected tonsils and large tonsils. The removal of infected tonsils, even in a young child, was a justifiable preventive measure, but the removal of tonsils merely because they were large—a normal condition in childhood—was to be deplored.

BEIT MEMORIAL TRUST FOR MEDICAL RESEARCH

A meeting of the trustees of the Beit Memorial Fellowships for Medical Research was held on July 12th, for the election of Fellows and other business.

The trustees expressed their deep regret at the recent death of Sir John Rose Bradford, F.R.S., who had been an original member of the advisory board in 1909 and had, together with the late Sir James Kingston Fowler, taken a most important share in advising Sir Otto Beit upon the foundation of the trust. Sir John remained on the Advisory Board for 12 years, and subsequently gave valuable service as a trustee for the last five years of his life.

Confirmation was given to the appointment of the Lord Macmillan as a trustee, and Prof. T. R. Elliott, F.R.S., was also appointed a trustee in succession to Sir John Rose Bradford. The trustees accepted with regret the resignation of Sir Charles Sherrington, F.R.S., from the advisory board after 24 years of service throughout which his wisdom and special knowledge had given invaluable aid to the work of the trust. They appointed in his place Dr. E. D. Adrian, F.R.S., Foulerton professor of the Royal Society.

The trustees noted with pleasure that two members of the advisory board had received honour recently from the King, Sir F. Gowland Hopkins being granted the Order of Merit, and Sir Patrick Laidlaw that of knighthood. Fellowships during the year 1934–1935 were held by 26 workers. Among the appointments gained during the year by past Fellows may be noted that of Dr. J. R. Marrack to the professorship of chemical pathology, University of London, at the London Hospital; of Dr. A. St. G. Huggett to the professorship of physiology, University of London, at St. Mary's Hospital; of Dr. W. P. Kennedy to the professorship of biology, Royal Medical College, Bagdad; and of Dr. F. H. Smirk to the professorship of pharmacology in the Egyptian University, Cairo. Dr. W. R. Aykroyd has been appointed director of nutritional research under the Indian Research Fund Association. Dr. S. Zuckerman was awarded the W. J. Mickle prize fellowship for 1935 of the University of London.

The Trustees did not elect this year a Beit professorial Fellow, but they hope to make such an appointment as soon as a suitable occasion arises.

The following elections to Fellowships were made:—

Senior Fellowship

Robert Hill, M.A. Camb. To continue his studies on the respiratory function of hæmoglobin. At the Physiological Laboratory and the Molteno Institute, University of Cambridge.

Fourth Year Fellowships

Robert Gaddie, B.Sc., Ph.D. Edin. To continue his research on the metabolism of heart muscle. At the departments of medical chemistry and materia medica, University of Edinburgh.

John Michael Robson, D.Sc., M.D. Leeds. To continue his work on the hormonic factors concerned in the maintenance of pregnancy and initiation of parturition. At the Institute of Animal Genetics, University of Edinburgh, or the School of Agriculture, University of Cambridge.

Frank George Young, B.Sc., Ph.D. Lond. To study the diabetogenic factors of the anterior pituitary gland. At the department of physiology and biochemistry, University College, London.

Junior Fellowships

Alexander Robertus Todd, B.Sc. Glasg., Ph.D. Frankfurt, Ph.D. Oxon. Carnegie research scholar 1928. Proposed research: The molecular structure of vitamin B_1. At the department of medical chemistry, University of Edinburgh.

Robert John Kellar, M.B., Edin., M.C.O.G., Leckie-Mactier Fellow in medical research 1934–35. Proposed research: The problem of nephritis and high blood pressure associated with pregnancy. At the London laboratories of the Royal College of Surgeons, and the obstetric unit, University College Hospital, London.

Norman Lowther Edson, M.B., N.Z. Medical travelling scholarship, University of New Zealand 1930. Proposed research: Fat metabolism and ketogenesis. At the Institute of Biochemistry, University of Cambridge.

Myer Head Salaman, M.D. Camb. Research on virus diseases under Prof. S. P. Bedson, F.R.S. At the London Hospital 1932–34. Proposed research: Investigation of the antigenic structure of the vaccinia virus. At the Lister Institute of Preventive Medicine, London.

James Davidson Fulton, B.Sc., Ph.D., M.B.Glasg. Chemist to the Manchester Committee on Cancer 1928-30. Proposed research: The experimental chemotherapy of malaria. At the London School of Hygiene & Tropical Medicine.

Adèle Helen Rosenheim, M.A. Camb., Ph.D. Lond. Grocers' Company Research Scholarship 1931–33. Proposed research: The chemical nature of antibodies, especially those in antityphoid sera. At the Lister Institute of Medicine, London.

All correspondence of Fellows and candidates should be addressed to Prof. T. R. Elliott, F.R.S., hon. secretary, Beit Memorial Fellowships, University College Hospital Medical School, London, W.C.1.

UNITED STATES OF AMERICA

(FROM AN OCCASIONAL CORRESPONDENT)

FINANCIAL AID FOR PUBLIC HEALTH

THE Congress has at length taken cognisance of the present inadequate provision for public health in large areas of the nation. Only 528 out of 3000 counties are served by full time officials, and even among these comparatively few have degrees in public health. The Social Security Act just passed by Congress makes provision for federal aid amounting to 8,000,000 dollars to be distributed through the public health service, and for a further 6,650,000 dollars to be distributed for maternal and child health and for crippled children through the children's bureau. The public health service is in the Treasury department under the special supervision of Miss Josephine Roche, assistant secretary of the Treasury. The children's bureau is in the Department of Labour. There will, however, be some attempt to coördinate the administration of these two funds both intended for public health purposes. The fact that the present assistant chief of the children's bureau is a physician will probably remove some of the antagonism formerly felt by the organised medical profession to work done by this bureau under the provisions of the Sheppard-Towner Act.

A meeting of State and territorial health officers was held in Washington on June 17th and 18th, at which agreement was reached with officers of the U.S. Public Health Service regarding standards of public health administration which must be met to justify reception of federal subsidy, the basis on which the 8,000,000 dollars would be allotted to the several States, and the qualifications of training which in future are to be required of public health personnel.

A qualified full-time State health officer must be in charge of the State health department receiving subsidy. The department must give adequate administrative guidance to local health services, and must include competent divisions of vital statistics, laboratories, epidemiology, and environmental sanitation. No subsidy will be allocated to any local health unit whose staff does not include at least one full time health officer, two nurses, one sanitarian (sanitary inspector), and one clerk. When more than one county is included in an administrative district there must be at least one public health nurse in every county.

Health officers in charge of an area having 50,000 or more population must have had at least a year's training in a course of public health which includes specified courses (including biostatistics and epidemiology), and which corresponds to a modern university training leading to the certificate in public health (C.P.H.). Health officers of smaller units must have specialised in public health work before they were 35 years of age. Preference is given to those who have had one or more years' experience in the general practice of medicine. All health officers who have not degrees in public health must be prepared to take post-graduate training. Provision is made under the Act to assist them in obtaining this training. It is realised however that present academic facilities will limit the number that can be trained in the immediate future. It is clearly intended that a standard equivalent to the British standard shall be reached as rapidly as the training facilities will permit. Standards are laid down similarly for the training of public health nurses and of sanitarians.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

EDINBURGH'S HEALTH

SOME interesting statistics are given by Dr. John Guy, medical officer of health in the annual report for 1934 on the health of the city of Edinburgh. The birth-rate for the year was 15·7 which shows an increase over the previous year. Of the total births 6·4 per cent. were illegitimate. The death-rate was 12·8. The infant mortality-rate was the lowest on record for the city, being 62 deaths for 1000 live births. The effect of re-housing tenants from condemned buildings is shown by the health figures for the Prestonfield re-housing area, to which the tenants in the St. Leonards improvement scheme were transferred en bloc. This has resulted in a reduction of the death-rate for this community from 21·9 in 1927 to 7·7 in 1934, a reduction of the death-rate from pulmonary tuberculosis from 1·5 to 0·3, and a reduction in the epidemic diseases death-rate of from 3·4 to 0·3. The greatest improvement was observed in the infantile mortality-rate, which in 1927 was 132 per 1000 births in the old area but only 28 per 1000 births in the new area in 1934. The problem of overcrowding is still acute, and the new cases of overcrowding notified during the year are almost equal in number to those which were dealt with by providing families with larger houses. The pulmonary tuberculosis death-rate for the year was 0·66 per 1000, which makes a new low record for the city, and is less than half the death-rate 34 years ago. 4530 patients were admitted to the City Hospital for infectious diseases. No case of diphtheria or scarlet fever occurred among the nursing staff, a feature which Dr. Guy attributes to active methods of immunization. In this connexion Dr. Guy emphasises the importance of the campaign for immunization against diphtheria. An arrangement has been made whereby all medical practitioners in the city can give this protection free of charge to all who apply. The arrangement whereby the professor of bacteriology acts as director of the bacteriological services has proved very satisfactory.

The work of the municipal general hospitals continues to increase, and nearly 6000 patients were treated during the year. The arrangement whereby there are resident students in the Western General Hospital has proved to be of great value. Dr. Guy went to show that the children now leaving school are physically and medically fitter than they have ever been, but that this improvement was not so marked in the case of those entering school for the first time. There is however a decided reduction in the incidence of rickets and tuberculosis. In 1907 5·8 per cent. of the boys and 7·8 per cent. of the girls entering school for the first time were found to have acquired deformities; the corresponding figures for last year were 0·5 and 0·4 respectively. Dr. Guy concluded that the Edinburgh statistics compared favourably with those of other large towns, and said that there can be no doubt that the steps taken to demolish overcrowded and derelict houses in the city are having a beneficial effect on the health and well-being of the community.

CORRESPONDENCE

TREATMENT OF TUBERCULOSIS OF THE LUNGS BY MEANS OF BI-LATERAL COLLAPSE

UNEXPLAINED DEATH

To the Editor of THE LANCET

SIR,—This history and description of a case of death occurring three months after the establishment of bi-lateral artificial pneumothorax treatment, is sent to THE LANCET because of the comparative rarity of such a catastrophe, and because I am quite unable to give any explanation why the patient succumbed.

Mrs.——, aged 45 years, was found to be suffering from Pulmonary Tuberculosis in 1928, on the occasion of a first and only hæmoptysis. She had previously suffered from quinsy, dengue, measles, and whooping-cough. All her ascendants, her husband, and her only child were free from tuberculosis.

A left artificial pneumothorax was induced in the Brompton Hospital in October, 1928, and she was then sent to the Frimley Sanatorium, and stayed there from February to October, 1929. Refills were continued during residence at home till 1932 when collapse was abandoned as all symptoms of disease of the lungs had subsided and skiagraphic examination of them failed to reveal any evidence of active disease. From 1932 onwards, she remained well until the middle of 1934 when expectoration of tubercle bacilli gradually returned and she began to lose weight. These symptoms did not abate with home treatment on sanatorium lines and she was readmitted to the Brompton Hospital on March 11th, 1935, when she was found to have a raised temperature—99° in the evening, under-weightness signs of æro-œdema, bronchial breathing and dyspneumonophony at the upper part of the left lung. On skiagraphic examination extensive infiltration, fibrosis, and excavation in the upper and middle zones of the left lung and moderate widespread infiltration in all zones of the right lung were found.

On March 13th, 1935, pneumothorax was re-established on the left side by thoraco-puncture at the angle of the scapula, after unsuccessful attempts had been made in the axilla. Owing to numerous adhesions the collapse induced remained small and mainly localised at the posterior part of the left lower lobe. On March 18th, 1935, a pneumothorax was successfully established on the right side and partial collapse was obtained; complete collapse being prevented by the presence of adhesions which were much less developed than on the left side. The patient remained in the hospital until May 17th, 1935, by which time simultaneous weekly refills were being given, the right chest receiving on each occasion 400 c.cm., giving a final mean pressure of −2, the left chest receiving 250 c.cm., giving a final mean pressure of + 1.

Her condition had improved very considerably by the time she left the hospital, all fever and expectoration having ceased, although the large cavity present at the apex of the left lung was only moderately compressed; she returned home to the country and she visited the refilling department of the Brompton Hospital each week for the next three weeks and had the same quantity of air introduced each time. At the fourth visit to the hospital on June 13th, 1935, she looked and felt very well; screening showed slight re-expansion of the right lung and the following refills were given: right lung 450 c.cm., giving a mean pressure of −2; left lung 250 c.cm., giving a mean pressure of +4. On her way from the hospital to South Kensington Station she began to feel so breathless that she considered it wise to return to the hospital, becoming ill shortly after admission. The intrapleural pressures were found to be: right +5, and left +15, and air was removed from each pleural cavity, the final pressures being: right −5, and left −1. Recovery was immediate but she was detained in the hospital over-night for close observation; when seen at 11 P.M. and in the early hours of the morning she seemed quite well, but when she awoke at 8 A.M., after a good night's sleep, she again became very ill and died suddenly.

Post-mortem examination was carried out by Dr. E. E. Atkin. Chest: bi-lateral pneumothorax; no effusion in either pleural cavity; strong adhesions over the upper part of each lung especially the left; universal pleural adhesions over the anterior and lateral surfaces of the lower left lung; the lungs were inflated through the trachea, under water, but no evidence of fistula could be found in either lung. On section, the right lung revealed fibroid tuberculosis at the apex and foci of recent tuberculosis infiltration in the lower parts; the left lung showed a large cavity near the apex containing pus and foci of tuberculosis infiltration in the lung tissue behind and below it. There was no pulmonary thrombosis. The heart showed no abnormality in muscle, valves, or coronary arteries; no abnormality was found in the brain and all other organs were normal except the larynx which showed slight ulceration of the left vocal chord.

The onset of shortness of breath and the increase of intrapleural pressures found after its onset on June 13th suggested that spontaneous pneumothorax had occurred, and the prompt recovery when air was removed confirmed this view. It was very remarkable that the patient should have had a comfortable night after the removal of air and yet should have died suddenly fourteen hours after such removal. At no time, whether at the second induction of pneumothorax or at any refilling, had she shown evidence of plural shock. There was no evidence that would lead one to suspect that she was a drug-addict.

I hope that some other readers of THE LANCET will be able to communicate to you an adequate explanation for the untimely end of this patient.

I am, Sir, your faithfully,

Harley-street, W., July 12th. H. BATTY SHAW.

THE FUTURE OF PHARMACY

To the Editor of THE LANCET

SIR,—In a letter in your issue of July 13th, under this heading, Dr. S. C. Dyke questioned a statement which I made in my address to the British Pharmaceutical Conference suggesting that it would be of assistance to the doctor if he could depend upon the pharmacist to undertake certain biochemical examinations. It is not to be expected that my opinions on this question will coincide with those of the Association of Clinical Pathologists. Nevertheless, without engaging in a controversy which is unlikely to lead either of us to alter our opinions, I may perhaps be permitted to record certain matters which are facts rather than opinions which led me to the suggestions contained in my address.

Firstly, the fields of physiology and biochemistry should not be, and to-day are not, the exclusive province of the medical profession. There are distinguished physiologists and biochemists who do not hold a medical qualification. Next, the medical qualification by itself, while conferring obvious advantages upon a worker in these fields, is itself no guarantee of competency in them. Much of the work is essentially chemical work, for which a chemical training and outlook are required. Thirdly, there are to-day pharmacists regularly engaged in the biochemical examination of pathological specimens both in private practice and in hospitals. Again, the pathological laboratory, as Dr. Dyke truly points out, is not the place where a complete diagnosis can be made. Such a diagnosis involves the services of more experts than the chemical pathologist alone, and it is for the physician in charge of the case to make the final diagnosis after he has received reports from the clinical pathologist, the radiologist, the bacteriologist and, it may be, other specialists. It is the function of no one of these to proceed to an *ultimate diagnosis.*

It is considerations such as these which lead me to the conclusion that the medical qualification, although of value, is by no means an essential for persons engaged in this work. I feel myself that one of the most unfortunate tendencies in the medical profession is this refusal to look beyond the pages of the Medical Register. Medicine is rapidly changing, and it is impossible to-day for the medical practitioner to become a specialist in every branch of knowledge which impinges upon medicine. The informed public may well look a little cynically upon a calling which refuses to look beyond its own boundaries and to accept competent qualified assistance, quite apart from quackery, which chances to be outside its own ranks.

I am, Sir, yours faithfully,

F. W. CROSSLEY-HOLLAND,
Chairman, British Pharmaceutical Conference.
Bloomsbury-square, London, W.C., 15th July.

PROGNOSIS OF SIMPLE MOLES AND MELANOTIC SARCOMA

To the Editor of THE LANCET

SIR,—In his article on this subject in your issue of June 15th Mr. Sampson Handley makes the statement that "Though melanotic sarcoma is fortunately a rare disease . . ." quoting the Massachusetts figures in support. The statement presumably refers to the incidence of melanomas amongst the white race in temperate countries; it is certainly not correct if applied to the dark-skinned races in the tropics of Africa. The following figures may be of some interest in this connexion . In these laboratories during the years 1930–35 (ending June 1935) 438 specimens were reported as malignant tumours and of these 31 were melanomas, which is approximately 7 per cent. All these melanomas occurred in Sudanese and were sent in from all parts of the Sudan. Eighteen were from the foot, 7 from other parts of the leg, 4 from the eye, 1 from the breast, and 1 from the tip of the index finger. Similar figures are reported from the Medical Research Laboratories, Lagos.[1] For the years 1930–33 90 malignant tumours were reported, of which 10 were melanomas, all from the foot. The Nigerian workers have previously drawn attention to the predilection of these tumours for the foot, and it is of interest to note a similar disproportionate frequency in the Sudan figures. I am unable to suggest any explanation of this finding, at least for the Sudan cases.

One is led to infer from the statements in the text-books that melanoma is a rare tumour in the negro race —e.g., MacCallum[2] states " . . . we were surprised to find that all the 10 cases of melanoma that were observed at autopsy here were in white persons, although in the course of the 12,000 autopsies in which these occurred the proportion of negroes is high." Ewing[3] says "In the negro melanotic tumours are rarely recorded, but on account of the difficulty of diagnosis it is probable that many are overlooked." The occurrence of melanomas in white or grey horses only was long ago pointed out by Virchow, and a somewhat dubious analogy is often drawn between this observation and the apparently greater incidence of melanomas in white persons. The Sudan and Nigerian figures quoted above are absolutely at variance with the *common belief that melanoma is a rare tumour* in the darkly pigmented races. In this connexion it is better to avoid the term negro, as although ethnologically the bulk of the Sudanese are not negro there occurs a considerable mixture of negro blood through the country.

I think it is reasonable to conclude that a tumour which constitutes from 7–12 per cent. of all malignant growths must be regarded as comparatively common; and indeed suggests a greater liability of the darker skinned races of Africa to this neoplasm.

I am, Sir, yours faithfully,

Khartoum, June 29th. E. S. HORGAN.

GOLD TREATMENT OF ASTHMA

To the Editor of THE LANCET

SIR,—In continuation of my letter which you published last August I would like to record our further progress in the treatment of asthma with gold preparations. A hundred cases have been treated, 60 of them at the Kasr-El-Ainy Hospital under the care of Dr. H. Abu Khatwa, resident registrar, and the sum total of our experience can be expressed in one sentence: In order to get the full benefit of the treatment, one must eliminate all obvious causes of irritation before instituting it; and unless this is done no effect whatever can be expected from the drug.

I feel sure that in all cases of failure there must have been some cause of irritation which we could not identify, and which has thus remained in operation and prevented success. The causes we have come across most often, and which were eliminated before the treatment was made successful, were: (1) Sinusitis (purulent or catarrhal), nasal polypi, and other irritative conditions of the nasal mucous membrane. (2) Sluggish liver—conditions spoken of by French authors as "insuffisances hépatiques." In these cases not only does the treatment fail, but the gold cannot be tolerated and complications of a dangerous nature may appear. Chronic cholecystitis and gall-stones can become contra-indications, leading to failure or intolerance. (3) Intestinal parasites (particularly amœba but also ankylostoma and ascaris). In some of our cases four injections of gold were given without the least response, but when we got rid of the parasite, the asthmatic attacks disappeared without any further trouble.

I must also say a few words about the complications that sometimes developed owing to intolerance of the drug. As mentioned in my first letter, fever was very common, especially in summer, but was never serious, and usually passed off in a few hours. The most important complication, however, is dermatitis, which may be very severe, and is accompanied by high fever. Happily we have had it only in two cases, and both ultimately recovered. Jaundice has appeared in two private cases, lasting about three weeks and then passing off. I still find extract of liver, given subcutaneously and accompanied by intravenous injections of thiosulphate of soda or magnesium (10 per cent.) in doses of 10 c.cm., to be the best treatment for all complications arising from intolerance of gold.

Of the 60 cases treated in the hospital 6 have shown relapses after a year's freedom from attacks; and so have 2 out of 40 in my private practice. In all these cases a second course of treatment has given lasting relief. Four of my private patients had heart diseases, and they were all relieved of asthmatic attacks after having stood very well a course of four injections each. For no apparent reason 6 of the 60 hospital cases and 6 of the 40 private ones did not respond at all to the remedy.

GOLD TREATMENT OF TUBERCULOSIS

To the Editor of The Lancet

Sir,—In reply to Dr. Shaw's criticism of our paper, we cannot see any force in his objection to the type of case we used for the test. Does he seriously consider that the administration of gold to our moribund cases and to cases in which the progress was eminently favourable would have improved the value of our statistics?

Actually in the most significant period, 1932–34, out of 299 cases 71 were hopeless and 81 were mild cases. The inclusion of these admittedly dilutes the statistical evidence for good or ill, but does not necessarily falsify it compared with the "no gold" series. As regards dosage there is no mystical significance in his figure of 5 g. considering our patients' weights varied between six and twelve stones. Some of our patients received less than this amount and some more, all depending on reactions and progress based on clinical and radiographical observations.

We did not mention our repeated radiographical investigations, as this is as much a routine of sanatorium treatment nowadays as taking a patient's temperature. Our paper was headed a statistical study and we confined our remarks to that aspect only. Dr. Shaw does not seem to be aware that Crysalbin and Sanocrysin are different trade names for gold sodium thiosulphate as he accuses us of giving all our injections *intramuscularly* (his italics). This compound is not suitable for intramuscular injection. Actually 78 per cent. of those treated received intravenous gold sodium thiosulphate. A very large number of publications favourable to gold treatment in tuberculosis by many "authorities" are totally devoid of any control series and are of no evidential value as to its benefit.

In spite of Dr. Shaw's castigation, we unrepentantly maintain that, if in a series of 299 cases one half receive a new treatment, some improvement on previous results should be shown, if the treatment is of any striking value, compared with a similar control series, more especially when we showed that the new treatment was applied during a period when the fatality of the disease was tending to fall in this age-group compared with the former group. When we find that in the pre-gold period quiescence or improvement of disease occurred in 66·2 per cent. of the patients treated by sanatorium methods, whilst during the period 1932–34 when half our cases received gold the corresponding figure was only 63·3 per cent., we cannot view our results with any satisfaction.

We are, Sir, yours faithfully,

B. A. Peters,
C. Short.

Pill, near Bristol, July 15th.

GOLD TREATMENT OF RHEUMATOID ARTHRITIS

To the Editor of The Lancet

Sir,—With the general tenor of Dr. Hartfall and Dr. Garland's article we find ourselves in complete agreement and we note they confirm our previous work in stating that chrysotherapy is the most important form of treatment in rheumatoid arthritis.

We at our clinics have always used the intramuscular method and we believe that fatalities can be avoided if these principles are borne in mind: (1) to start with small doses; (2) to observe carefully the patient's reaction and, should there be any, to avoid larger doses; (3) to use the intramuscular route; (4) to space the doses correctly. We have described our technique fully in the *Practitioner* of June, 1935.

We believe that small total doses frequently administered are preferable to larger massive doses, and it has been our practice to give courses with a maximum of 1·3 g.—this to be followed by an interval of 4–6 weeks before the second course is attempted. It must be emphasised that the treatment is a long one and will last *at least* nine months.

By these methods we have had no anxiety in any case—though there have been skin reactions of various types in a few cases. We agree with Dr. Hartfall and Dr. Garland that thiosulphate, liver, &c., seem of little use once there has been a reaction, but are of the opinion that collosol sulphur in drachm doses at night is a very helpful adjuvant.

We feel the analogy of syphilitic treatment is very apt. Arsenobenzol is also dangerous if given unsuitably or in large doses. Skin and general reactions likewise occur—and like chrysotherapy the treatment is long and numerous courses are required.

In conclusion, our results to date which we hope soon to publish are most encouraging. Several completely disabled cases are now resuming their activity though perhaps in a modified form. Patients themselves who are very good judges of their progress in this condition state they feel better, have less pain and more movement. Clinically there can be no doubt at all of the value of the treatment in many of these intractable cases—many of whom had had all the usual remedies over a long period of time before chrysotherapy. It is only fair to add that chrysotherapy is a method and we use in addition physiotherapeutic measures where indicated. Many of our cases, however, have not had this form of treatment.

We do not think gold is more dangerous if used as above than arsenic compounds or even digitalis; but like all therapeutic measures the physician must learn the uses of his drug—in the right case its dose and its reactions.

Finally, we would add that although no curative measure is obtained in osteoarthritis, the treatment seems to relieve pain and improve the general condition. We must stress the point that some pain is experienced during treatment—indeed many of our best results have suffered in this way. This is an indication to continue and not to give up. We feel the last attitude is responsible for some of the unsuccessful results which have been obtained.

I am, Sir, yours faithfully,

Gerald Slot,
P. M. Deville.

Harley-street, W., July 13th.

AN EPIDEMIC OF HERPES

To the Editor of THE LANCET

SIR,—Herpes of the lip and face is not perhaps unusual among individuals exposed to sun rays, but an epidemic appears to me of some interest. The manager of a clothing factory asked for my advice, as 14 of his employees were suffering from swollen lips and a rash round the mouth. Two had been to hospital and reported that they had been told they had erysipelas.

On inquiry at the factory the condition was obviously one of herpes of the lips and face. The employees on the previous Saturday had been taken for a day's outing to the sea, returning at midnight in an open charabanc. The occurrence of this condition among approximately 24 per cent. of persons exposed would appear to be high. The sufferers were of varying types of complexion, and some had bathed, some had eaten shell-fish, and some had done neither. All complained of the condition commencing with irritation on the Monday evening.

I am, Sir, yours faithfully,

JOHN C. BRIDGE,
Senior Medical Inspector of Factories,
Home Office, S.W.
July 13th.

HEADACHES

To the Editor of THE LANCET

SIR,—Respect for the views of Sir Edmund Spriggs, and admiration for the contents of his article on headaches, do not prevent me asking for a further explanation of certain categories into which he places the nervous patient. He distinguishes three groups: the first being "neurotic" (subdivided into "nervous" and "neurasthenia"); the second being "tired" (subdivided into "nervous exhaustion" and "overtired"); and the third being "worried," with four subdivisions. His brief descriptions do not convey any clear idea of symptomatology.

I feel sure there are many who would appreciate a more complete discussion of his terminology, explaining in particular what he means by "neurotic," "nervous," "neurasthenia," and "nervous exhaustion."

I speak, Sir, as a clinician anxious to understand something of the value of the nervous factor. Sir Edmund Spriggs's classification does not seem in accordance with any modern concepts. Perhaps he will define what his terminology involves.

I am, Sir, yours faithfully,

Wimpole-street, W., July 6th. JOSEPH GEOGHEGAN.

BLEEDING OF TRANSFUSION DONORS

To the Editor of THE LANCET

SIR,—May I make the following observations on the method of bleeding transfusion donors described by Dr. Marriott and Dr. Kekwick in your last issue? (1) In my experience, a special needle requiring the use of novocain for its insertion is never necessary, an ordinary wide-bore serum needle being perfectly adequate if carefully chosen. With this, a pint of blood is easily withdrawn without the use of suction. In view of the fact that he may be called upon again within a short period, a volunteer donor should not be asked to give more than this. It may also be mentioned that he is always informed by the Red Cross Society of the amount he has given. (2) In my own experience, though suction may with advantage be employed, the use of too drastic a suction defeats its own end. The suction of a rubber bulb of moderately thick wall is all that is necessary to give a stream of blood the size of an ordinary lead pencil. Stronger suction cannot make a vein yield more blood than its lumen will carry, and only tends to suck its walls together, thus diminishing or even occluding the lumen. It also gives rise (as I can testify from my own experience as a donor) to a highly unpleasant vibration in the vein, the walls of which are converted into a sort of reed by the suction. This happens frequently, even if the suction is only that provided by a rubber bulb with a fairly thick wall.

While suction may be employed with advantage, I cannot agree that it should be more than that provided by a rubber bulb such as Dr. Marriott and Dr. Kekwick condemn.

I am, Sir, yours faithfully,

J. W. SHACKLE, M.R.C.S., L.R.C.P.

Grosvenor-street, W., July 15th.

"ULTRA SHORT WAVES"

To the Editor of THE LANCET

SIR,—In view of the interest in claims concerning the so-called specific action of "Ultra Short Waves" (i.e., an action not accountable as a heat effect, and having a short wave length dependence), and more especially that high-frequency currents corresponding to a wave length of 3·4 metres have a specific effect on rat tumours, Dr. H. J. Taylor has carried out a series of observations at the St. John Clinic and Institute of Physical Medicine which led him to conclude that there is no such specific effect. Wave lengths of 3·4 metres and 4·5 metres are effective in destroying small rat tumours growing in the flanks of the animals, at the same time producing damage to the surrounding tissues.

The tumours may be necrosed equally well by both these wave lengths and also with vastly different doses of ultra short waves. For example, a small dose of U.S.W. without cooling is just as effective as a high dose with cooling. The results will be published later in detail, but I would like to point out that the conclusion reached is that the effect is a heat effect, a conclusion which confirms that of Dr. A. Eidinow, based on the nature of the pathological changes produced by ultra short waves.

I am, Sir, yours faithfully,

London, S.W., July 15th. LEONARD HILL.

THE INCIDENCE OF PROCTITIS IN GONORRHŒA OF FEMALES

To the Editor of THE LANCET

SIR,—I was much interested in the article on this subject by Dr. Clements and Dr. Hughes in THE LANCET of July 6th, 1935. I have been aware of the danger of missing this infection ever since I have had charge of the female V.D. department at Guy's from 1917. It has always been part of the routine at this clinic to take films and cultures from the rectum in suspected cases of rectal gonorrhœa and, in more recent years, the majority of cases attending for vaginal discharge have had initial rectal tests taken. The percentage of positive cases has been markedly lower than that obtained at St. Thomas's. This may be due to the fact that if the initial rectal tests are negative and no further signs and symptoms develop, the rectal tests are not repeated until final tests for cure are made. In the definitively positive cases of rectal infection, the patients almost invariably have symptoms such as discharge, soreness, and feeling of weight and "piles." A small inflamed tag at the anus leads one to suspect rectal gonorrhœa. In suspected cases a small proctoscope is passed and material taken from obviously infected parts, which, at the same time, are touched lightly with solid $AgNO_3$. This treatment is followed up by the frequent use of suppositories of acriflavine or protargol.

In future, intermediate rectal tests will certainly be taken, as from the report from St. Thomas's Clinic it would seem that possibly cases have been overlooked.

I am, Sir, yours faithfully,
MORNA RAWLINS.
Devonshire-place, W., July 16th.

THE UNHAPPY COLON

To the Editor of THE LANCET

SIR,—Dr. Hurst would have us regard all cases of constipation as due to inefficiency of the conditioned reflex established in infancy, by sitting the child on the pot and maintained by the familiar associations that in later life supersede and replace this earlier stimulus. In his opinion, therefore, humanity must be educated in order to carry out efficiently this physiological act.

That the act is a reflex one is, of course, true. But why have to call on artificial stimuli? Surely the periodic activity of the colon from *start to finish* is the natural response to the taking of food. Why should the gastro-colic reflex action end at the pelvi-rectal junction? The upper valve of Houston may have some value in promoting control of the final expulsive act and throw less strain on the anal sphincter, but not being a true sphincter it cannot be intended to regulate the output in the manner Dr. Hurst describes.

Observation of the habits of infants before they are introduced to the once-a-day pot, of humanity in its more primitive state and of the highest apes, shows that the wave of contraction set up in the colon in response to the taking of food suffices to fill the rectum and that there is no obstruction to the completion of the act. Inhibition is deliberately set up in the nurseries of civilisation and maintained in early life, and this is the real origin of constipation.

I am in thorough agreement with Dr. Hurst as to the perniciousness of the habitual aperient. But education must be along the lines of suitable dietary from infancy onwards, not in setting up artificial stimuli and "conditioning" a natural process. After all, we most of us have an efficient anal sphincter to enable us to cope with the requirements of decency and order.

I am, Sir, yours faithfully,
S. HENNING BELFRAGE.
Seymour-street, W., July 16th.

PUBLIC HEALTH

Another Report on Maternal Mortality and Morbidity

AT a time when maternal mortality is much under discussion the publication of a report[1] by two medical officers of the Department of Health for Scotland is particularly opportune.

The authors, Dr. Charlotte Douglas and Dr. McKinlay, assisted by a clinical subcommittee, base their findings on an analysis of 2527 maternal deaths in Scotland since Oct. 1st, 1929, and an inquiry into all births during a six-monthly period, to the number of 39,205. The analysis of the maternal deaths follows the lines of the interim and final reports of the Ministry of Health's Departmental Committee and the results obtained are similar. The proportion of deaths attributed to various causes do not differ except that those for abortion and for eclampsia are somewhat lower, and for the other toxæmias of pregnancy higher, than in England and Wales. Among the "associated deaths,"—i.e., those due to diseases aggravated by pregnancy—the proportion attributed to renal disease was very much higher than in England. The "primary avoidable factor" was evaluated as in the English series and the percentage of "avoidable" deaths was considered to be 58·7, as against 46 in England and Wales and 65·8 in New York.[2] Allowing for personal variations in the arbitrary standards chosen, this confirms the view that about half of the maternal deaths were "avoidable." It is necessary to emphasise, however —and the report is not very clear on this—that it by no means follows that half the mothers would have been saved if this primary departure from the optimum procedure had been avoided. For example, a death from obstructed labour due to contracted pelvis would be classed as avoidable if the patient had had no antenatal care, but it cannot be assumed that such care would in fact have saved her life; she might have died during a Cæsarean section. At the same time the case-histories reproduced leave no doubt that maternal mortality in Scotland could be largely reduced.

Of the 58·7 per cent. of "avoidable" deaths, 21·6 were attributed to the negligence of the patient, and 37·1 to faulty technique of the attendant (including doctor, midwife, and institution). The patient's responsibility usually lay in failure to obtain antenatal care, and in 28 per cent. of fatal cases adequate supervision was lacking—more often than not because of the patient's indifference. In this group the largest subdivision is made up of cases of chronic renal disease, the insidious and painless nature of which does not force the patient to seek medical aid. Some of the women who died had refused therapeutic abortion, and it is noteworthy that in none of these cases did the fœtus survive. The investigators find that the number of antenatal beds available was "grossly inadequate," and although they did not observe that lack of food was a factor in maternal mortality, they bring out the difficulty of providing a special diet under home conditions—a difficulty which made institutional treatment a necessity in a majority of cases of the toxæmias of pregnancy.

Of the women who died at confinement (the "intranatal" class) it is stated that "in the main groups of sepsis, failed forceps, shock, and post-partum hæmorrhage, there is little doubt that in the majority an undue desire to 'hurry' the confinement was at the root of most of the troubles." Where the attendant was not at fault it was the relatives rather than the patient herself who refused to coöperate—a statement which will be borne out by every general practitioner who undertakes midwifery. As to the postnatal group two points are made. First, that obvious sepsis was often unacknowledged and the patient kept at home far too long; and secondly, that cases have been traced to children recently discharged from hospitals for infectious diseases and other persons with septic foci.

---

[1] Report on Maternal Morbidity and Mortality in Scotland. By Charlotte A. Douglas, M.D., and P. L. McKinlay, M.D. 1935. Edinburgh: H.M. Stationery Office.

[2] Maternal Mortality in New York City. By the N.Y. Academy of Medicine, New York: The Commonwealth Fund. London: Oxford University Press. 1933.

General comparisons between the group of deaths and the control group of confinements throw a new light on the effect of parity on risks of pregnancy. It appears that while primiparæ have an excess risk amounting to 13 per cent., the fifth and subsequent pregnancies show *a mortality greater than the first*, and increasing steadily with the number of pregnancies. (It has hitherto been thought that it is not until the eighth pregnancy that the risks are greater than the first.) It is concluded that the effect on the maternal mortality-rate of a falling birth-rate is therefore generally favourable rather than the reverse, although certain causes of death such as eclampsia and accidents of childbirth would be adversely affected by the increase in the relative number of primiparæ. Other conclusions of general interest are that overcrowding has no adverse influence, rather the reverse, and that bad health before pregnancy and a deterioration of health during pregnancy was much more conspicuous among the women who died than among the others.

A consideration of the maternal mortality-rates in Scotland from 1911–30 shows the highest rates to have been in the three border counties and the lowest in equally rural, widely separated areas. Regional comparisons, however, show less variation than in the death-rates from many other diseases. There are gross variations in the rate from year to year, suggesting that comparatively static factors such as the standard of obstetric care are not so important as other considerations, among which might be meteorological conditions or the prevalence of infectious diseases.

The recommendations made by Dr. Douglas and Dr. McKinlay include a general warning against the dangers of undue publicity, and they support a closer linkage between midwives and local authorities "as, for example, by a local authority midwife service." Antenatal, intranatal, and postnatal supervision should be afforded by the same medical attendant wherever possible, and "if, at any stage, a pathological condition is failing to respond to treatment, and if the necessary steps for the patients' safety cannot otherwise be taken, the medical officer of health should be informed at once." Local authorities should consider the institution of a voluntary system of notification of pregnancy, as at Huddersfield, and grants of milk should be made rigidly conditional on adequate antenatal supervision. "It is for consideration whether it is practicable to make the obtaining of adequate antenatal care an essential condition of payment of maternity benefit." As far as the conduct of confinements is concerned it is strongly recommended that, wherever practicable, the advice of a recognised obstetrician should be obtained before any procedures other than minor instrumental or manipulative interference is attempted. Practical instruction in contraceptive methods should be available for women for whom further pregnancies would be dangerous.

Food-poisoning at Nelson

Dr. R. G. Markham, medical officer of health for Nelson, Lancashire, provides us with information about the recent outbreak of food-poisoning in the town. The first intimation of the outbreak was, he says, received on June 28th, and the onset of all the cases seems to have been within the period June 28th to July 1st. So far as can be ascertained about 173 cases occurred, and inquiries showed a common source of infection in cooked meats (pressed beef, stew, stew and cow-heel) which had been made up at one central depôt. The unsold remainder of the suspected carcass of beef was seized and portions sent for bacteriological examination, and after this carcass and the prepared foods had been withdrawn from sale and destroyed the outbreak subsided. The illness began from 12 to 24 hours after consuming the food, the symptoms being *acute abdominal pain accompanied by vomiting and diarrhœa.*

There were three deaths in Nelson, all on July 4th, and bacteriological examination carried out by the Ministry of Health revealed the presence of *Bacillus aertrycke* in all the organs of those who died. This bacillus was also isolated from specimens of food and beef sent for examination.

Anthrax in a Shaving-brush

The inconspicuous vigilance of the public health service is illustrated by a series of events which came to light at an inquest last week in London on a man named John Banks who died from anthrax on July 6th. A malignant pustule had developed on his cheek on July 3rd, and his shaving-brush was found to contain anthrax spores and bacilli. According to the widow, the brush had been bought at least two years previously and it proved somewhat similar to—though not definitely identifiable as—a brush missing from a consignment of twelve seized in June, 1932, all of which were found to contain anthrax spores. The fact that this consignment was infected was ascertained when a man died from anthrax contracted from a brush bought in Stepney, and it was then discovered that some from the same batch had been sold to two shops in Lambeth. It proved possible to collect all of these except one, which had been bought the day before by a chance customer who could not be traced. The shop from which it was sold is in the same street as Banks's home and only two or three minutes' walk distant. In 1932, when the missing brush could not be found, the hospitals in the district were warned to be on the outlook for a malignant pustule in order that no time should be lost before serum was given, but as no case occurred, it was believed that the customer was not a Lambeth resident.

Dr. A. G. G. Thompson, medical officer of health for Lambeth, to whom we are indebted for these particulars, informs us that considerable difficulty was experienced in tracing the source of supply to the wholesale dealer in Stepney in 1932, but as the result of careful inquiry it transpired that a shopkeeper now in Lambeth bought the brushes shortly after the war. They were overlooked at the back of a drawer, and when his business in Stepney was given up in 1930 they were sold with the rest of the stock. The original owner stated that he had intended to destroy them but forgot to do so. The country of origin had also been forgotten, but from various indications there seemed little reason to doubt that they were of German or Czecho-Slovakian origin.

A possible fault in the chain of evidence is that John Banks shaved with the brush at least once after the pustle was noticed, and it is arguable that the brush was infected from the pustule and was therefore not the primary cause. Banks was a small cobbler, and had purchased some leather on July 2nd. As the leather was tanned and dressed ready for soling, it did not seem to be a likely source of infection, but samples nevertheless were taken for examination with the expected negative result. Banks almost always shaved himself, and the last time he had been shaved by a barber was at least a fortnight before the onset of his illness; after inquiry no suspicion was attached to the barber's utensils. Hence the shaving brush appears to have been the source of the disease; but its prolonged use without giving rise to infection is amazing.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 6TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1485; diphtheria, 826; enteric fever, 49; acute pneumonia (primary or influenzal), 448; puerperal fever, 43; puerperal pyrexia, 107; cerebro-spinal fever, 16; acute poliomyelitis, 9; acute polio-encephalitis, 1; encephalitis lethargica, 4; dysentery, 11; and ophthalmia neonatorum, 95. No case of cholera, plague, or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 9th was 2685, which included: Scarlet fever, 768; diphtheria, 984; measles, 40; whooping-cough, 386; puerperal fever, 25 mothers (plus 8 babies); encephalitis lethargica, 271; poliomyelitis, 1. At St. Margaret's Hospital there were 25 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there were no deaths from small-pox or enteric fever, 12 (0) from measles, 1 (1) from scarlet fever, 18 (3) from whooping-cough, 19 (0) from diphtheria, 36 (7) from diarrhœa and enteritis under two years, and 13 (0) from influenza. The figures in parentheses are those for London itself.

Of the fatal cases of measles 5 were in Liverpool and 3 in Sunderland. Liverpool also reported 3 deaths from diarrhœa and enteritis, and there were 3 others in Hull and 2 each in Manchester, Sheffield, Birmingham, and Stoke-on-Trent. Three of the deaths attributed to influenza were in Manchester and 2 in Huddersfield.

The number of stillbirths notified during the week was 265 (corresponding to a rate of 37 per 1000 total births), including 37 in London.

PANEL AND CONTRACT PRACTICE

A Health Insurance Scheme for British Columbia

It seems likely that British Columbia will be the first of the overseas dominions to adopt compulsory health insurance. The question was considered some years ago by a Royal Commission, who in 1932 reported that they were satisfied that the people of British Columbia were "overwhelmingly in favour of a compulsory health insurance and maternity benefit scheme," and recommended that such a scheme should be established at an early date. The government of the province have since given the subject the most careful study from all points of view, and have now produced a draft Bill, which is intended to serve as a basis of discussion by all interested parties with a view to formulating a definite measure for adoption in the next session of the legislature. The Bill, which is accompanied by an explanatory memorandum, is evidently the result of some hard thinking, and it presents points that merit the attention of all who are interested in the progress of health insurance.

The explanatory memorandum emphasises the need for health insurance. It is believed that the conditions in the province do not differ materially from those prevailing in the United States as found by the extensive researches of the Committee on the Costs of Medical Care, which showed that while 1385 days of hospital care per year were required for every 1000 persons, only 746 days were actually given; that 5650 medical attendances were required as against 2391 given; and that although all the 1000 persons required dental care during the year only 241 received it. The position of the persons and agencies providing medical care is also unsatisfactory. In 1933 nearly one-half of the doctors engaged in private practice in British Columbia and 69 per cent. of the dentists had net incomes of less than $2000 (£400). And it is stated that "hospital boards throughout the province are at present at their wits' end as to how they can finance their institutions."

To remedy this state of things the Government propose to set up a health insurance system to be administered by a central commission, which will consist of five government officials, including two doctors—the provincial health officer, and the director of medical services. There will be two chief executive officers, both of whom will be members of the commission: the administrator of health insurance, who will be responsible for the business administration and enforcement of the law, and the director of medical services, who must be a qualified medical practitioner and who will organise, direct, and control the provision of the medical benefits granted under the scheme. Both officers will be appointed by the Lieutenant-Governor, but the appointment of the director of medical services must be with the approval of the College of Physicians and Surgeons of British Columbia. The commission will be advised by an advisory council representing the various interests concerned, and there will be a medical committee, nominated by the College of Physicians and Surgeons of British Columbia, charged with important functions in relation to the discipline of the medical service, and similar committees representing dentists, pharmacists, nurses, and hospitals.

Under the scheme insurance may be applied to such classes of employees earning $200 per month or less, and their dependents, as may from time to time be determined by the commission. Persons working on their own account and earning not more than $200 per month may insure as voluntary contributors, and the medical benefits of the scheme may be extended to destitute persons and their dependents. The employee will pay a contribution not exceeding three per cent. of his wages, and the employer will contribute an amount equal to two-thirds of that paid by the employee. The Government will make contributions sufficient to cover the cost of medical benefits provided for the destitute and half the cost of administering the scheme. The insured persons, including the destitute, will be entitled to an extensive range of medical benefits, comprising general practitioner, maternity, specialist, dental, nursing, laboratory, and pharmaceutical services, hospital care, and such preventive services as may be decided upon by the commission. For insured persons other than the destitute there will be a cash benefit payable during incapacity for work, beginning after the first week of incapacity and continuing for a maximum period of 26 weeks.

Payment will be at the rate of one-half the wages ordinarily earned.

The Bill provides that all qualified doctors, dentists, nurses, and pharmacists shall have the right to give professional services under the scheme if they wish to do so, and the insured persons will be free to choose any doctor, dentist, nurse, and pharmacist on the list of those who have undertaken to serve. These rights may, however, be modified in sparsely populated districts in order to guarantee a satisfactory service. It is estimated that the annual cost of the medical benefits will be $12·50 (50*s.*) per head, of which $3·40 will be set aside for the remuneration of the general medical practitioners, who may be paid either on a capitation or an attendance basis. But for the treatment of the destitute, who now form about one-fifth of the persons who would be eligible for insurance, payment will be at half rates, which the explanatory memorandum states "will not be unfair to the persons and organisations providing medical service, for at present they are doing a great deal of totally unpaid work for the indigents, and there is every reason to believe that, for most medical services, this arrangement can be made."

The inclusion of the destitute among the persons for whom treatment is provided under health insurance arrangements is a feature of the British Columbia scheme that is of special interest, for it carries into effect the policy advocated by the British Medical Association for adoption in this country, although it has not been suggested here that doctors should be paid at lower rates for the treatment of the destitute. Another interesting feature of the scheme is that it will be administered direct by a central commission without the interposition of approved societies or insurance committees. It is thought that this will effect such economies that the cost of administration will not exceed 10 per cent. or possibly 8 per cent. of the cost of the benefits. The draft Bill confers upon the commission wide powers to modify the scheme in various important respects, such elasticity being considered essential to the successful working of an extensive and elaborate system of medical services in a country where the geographical and social conditions vary so widely as in British Columbia. The commission may, for instance, by regulations require insured persons, other than the indigent, to pay as much as one-quarter of the cost of the drugs and appliances prescribed for them. A similar requirement has been adopted in several European countries to check the extravagant use of medicaments. There are other noteworthy points in the scheme, and those responsible for preparing it may be congratulated on their courageous and competent handling of a highly difficult subject.

Some Statistics

An examination of the quarterly statistical statement issued by the London committee is worth while if only to bring to mind the magnitude of the task of providing medical benefit for the insured population. Of the 1,888,956 insured persons in London on March 31st 1,760,219 were included in doctors' lists, 15,739 of them being the resident insured staffs of hospitals and similar institutions: 140 persons were required to make their own arrangements for the receipt of medical benefit, and 896 were allowed to do so; the former are exempt persons whose total income exceeds £250 a year (they pay no contributions but their employers do) while most of the latter are the employees of a hospital, the remainder being in the main persons who desire to obtain homœopathic treatment and others who for various reasons are allowed to obtain treatment from non-insurance doctors. There were 2060 general practitioners and 126 medical officers of institutions on the medical list, who during the quarter notified 65,308 acceptances but suffered 68,105 removals from their lists. The number of medical cards issued was 122,986. Forms of medical record recovered from practitioners numbered 66,472. 7013 insured persons applied for authority to change their local doctors but nearly 2000 of them changed their mind, for only 5061 eventually transferred, this number representing 0·287 per cent. of those whose names were included in doctors' lists. For the twelve months ended March, 1935, 17,812 so transferred, representing a comparable percentage for the year of 1·01.

The pharmaceutical service for the county is provided by 986 chemists in general business, 54 in institutions, and 12 other persons, a total of 1052 contractors who are responsible for 1299 shops within the county and 340 shops elsewhere where London prescriptions may be dispensed. The number of such prescriptions dispensed during the quarter was 2,388,506, costing £77,484 17*s.* 6*d.*, the average total cost per prescription being 7·79*d.*, while the average cost of the 1·35 prescriptions issued per insured person was 10·55*d.*

Insurance doctors still issue prescriptions for appliances which are not "prescribed appliances," and during 1934 a total of 547 such prescriptions had to be disallowed, to the dismay of the doctors who had to be surcharged with their value. The favourite articles in this connexion are eye shades (one-fifth of the total); others in order of popularity are finger- or thumb-stalls, capsicum wool, corn pads or adhesive felt, syringes, glass tubes and rods, down to safety-pins and tweezers. It should be borne in mind that while there is nothing to prevent a doctor from prescribing any drug, however costly, which is reasonably necessary for the adequate treatment of his patients, appliances may be ordered only if they are included in the list of "prescribed appliances" which will be found in the Second Schedule to the Regulations or in the National Formulary.

Housing Schemes and Surgeries

The housing committee of the Leeds Corporation recently asked the local panel committee to assist them in allocating special houses which are being erected for a limited number of doctors on the new housing estates. It was realised that doctors whose practices covered slum clearance areas were suffering hardship but the intention of the corporation to give a monopoly of surgery accommodation to certain doctors, and the consequent restriction of free choice of doctor to insured persons, gave rise to natural objections. Leeds appears to have been clearing slums somewhat drastically, so much so that in one case four-fifths of a practitioner's patients were affected. In one of the new colonies it was estimated that there would be about 3000 houses and some 15,000 people involved; four houses were being specially erected for doctors and dentists and the panel committee were asked to recommend the proper practitioners to whom the accommodation might be offered—a sensible request by the corporation but an embarrassing task for the panel committee. The position is complicated by the fact that doctors who have already taken surgery accommodation on the new estates have done so under the explicit statement of the corporation that the conditions were only temporary and subject to the tenancies being at the decision of the housing committee; clearly this arrangement must be altered in the direction of granting leases for a reasonably long period so as to attract the right type of practitioner. Meanwhile the result of the panel committee's deliberations will be awaited with interest.

A Final Certificate and the Consequences

The London medical service subcommittee has recently dealt with a curious complaint against a doctor. The insured person has been incapacitated almost continuously since 1931, suffering from pulmonary fibrosis and neurasthenia and receiving monthly certificates, but he has been able to work for about a fortnight at Christmas time each year as a temporary post-office sorter. In 1934 he worked from Dec. 14th to 26th and on Dec. 15th he induced the doctor to "sign him off" although the doctor demurred and eventually told him that if a final certificate were issued he would decline to certify him again as incapable of work. The insured person however applied for a certificate on Dec. 29th alleging that since the termination of his temporary work he had again become ill. The doctor declined, whereupon the man obtained treatment and certificates from another doctor, and on Jan. 18th a regional medical officer examined him and found him incapable of work; so on Jan. 21st and 24th he again consulted his doctor who prescribed for him but again declined to issue a certificate. Later he gave written consent to the insured person's transfer to the other doctor's list. The subcommittee stated that it was clear that the whole of the difficulty had arisen out of the insistence on the part of the insured person that he should be provided with a final certificate. There was no evidence to suggest that his condition between Dec. 14th and 26th, when he was doing his annual temporary work, was different in any essential respect from that obtaining during the remainder of the year. There was very little doubt that the sole reason for the insured person's application for a final certificate in this case was in order that he might benefit financially as a result of the wages he would receive as a temporary sorter being in excess of the amount which he would have received by way of disablement benefit. But the doctor had been at fault in issuing a final certificate after the man had gone to work and had committed an error of judgment in saying that he would not issue another certificate. A warning as to the necessity for a strict compliance with the medical certification rules was issued to him. With regard to an allegation that the doctor failed to examine the patient on Dec. 29th the subcommittee were of opinion that, being well aware of the history of the case, and having issued a final certificate on Dec. 15th the doctor was not satisfied on Dec. 29th that any material change in the man's condition would be demonstrated by a detailed examination. It appeared to the subcommittee that the insured person had proved by his own action in accepting work that he was capable of work, and, in these circumstances, they did not think he had any cause for complaint that the doctor refused, on being satisfied that there was no change in his condition, to issue a further certificate of incapacity. The committee adopted the recommendation that the complaint had not been substantiated, but that the doctor had been at fault in issuing a final certificate after the insured person had resumed work. The insured person accordingly has to pay the other doctor's bill, and the doctor who had the trouble of defending his actions will probably insist in future that certificates shall express his own opinion, and not necessarily the desire of his patients, however insistent these may be.

OBITUARY

ALFRED HENRY SPURRIER, L.R.C.P. Lond., C.M.G., O.B.E.

THE death is reported from Zanzibar on July 5th of Alfred Henry Spurrier, whose name is so closely connected with the government and medical administration of Zanzibar. He was born in Colyford, Devon, in 1862, and educated at Guildford Grammar School and the London Hospital Medical School, whence he took the diploma of L.R.C.P. London in 1887. He was for a period at the Gregorian University in Rome, but his long career in the east commenced with his appointment as medical officer to the Eastern Telegraph Company's cable ships in which capacity he assisted in the special deep-sea survey off the mouth of the Congo in the cable ship *John Pender*. He was appointed medical officer at the Company's station in Zanzibar, was present at the bombardment of Zanzibar in 1896 and was decorated by the Sultan for his services. In the following year he conveyed into German territory a usurper and his family, and conducted a tour with the Sultan through South Africa. He became physician in extraordinary to the Sultan who bestowed upon him various decorations, while he acted also as medical superintendent of "Prison Island" sanitary station and as editor of the *Zanzibar Gazette*. Dr. Spurrier was appointed O.B.E. in 1918.

HORACE MANDERS, M.D. Brux., F.R.C.S. Eng.

THE death occurred on July 5th at Chesham Bois of Lieut.-Colonel Horace Manders in his eighty-third year. He was born in Canterbury, the son of Major Thomas Manders, and educated at Marlborough, whence he went for his medical education to St. Mary's Hospital, London. There he was house surgeon and afterwards house surgeon at Canterbury Hospital. He studied for a time at the Beaujon Hospital, Paris, became interested in electrotherapeutics, and held an appointment for a time in this subject at the East London Hospital for Children. He was at one time medical officer at the hospital at Dvinsk, Latvia, while during the Boer War he saw considerable service in South Africa and was made an honorary captain in the army, and held the rank of lieut.-colonel in the 4th Battn. of the Royal Berkshire Regiment. Colonel Manders married Louisa, daughter of the late Mr. H. P. Goode of Haverfordwest and Colonel Horace Craigie Manders, A.D.C. to the Viceroy of India, is his son.

DAVID SAMUEL, M.R.C.S. Eng., L.R.C.P. Lond., J.P.

THE death occurred recently at Skewen of Dr. David Samuel, who was well known both for medical and public services in South Wales. He was born at Llanelly in 1868, was educated at the Athenæum school, a school in Llanelly at that time, and went to St. Mary's Hospital, London, for his medical education. He qualified with the English double diploma in 1869, and after practising for a short time at Port Talbot settled down at Skewen, where for the rest of his professional life he carried on successful general medical practice, giving special attention to ophthalmic work. He had a keen clinical instinct, was devoted to his work, and had the faculty of becoming the friend as well as the doctor to many of his patients. He was medical adviser to several local industrial concerns, including the National Oil Refineries and the British Tanker Company, while he also interested himself in the work of the St. John Ambulance Brigade and established the first Red Cross Brigade in the Neath division, which gave conspicuously good service during the war. He was J.P. for the county of Glamorganshire.

Dr. Samuel married Edith, second daughter of the late Richard Richards, of Aberavon, who survives him.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

In the House of Lords on July 10th the Housing (Scotland) Bill was read a second time.

In the House of Commons on July 10th, the St. Bartholomew's Hospital Bill was read a second time.

The West Riding of Yorkshire Mental Hospitals Board (Superannuation) Bill was read the third time.

In the House of Commons on July 12th, the University of Durham Bill passed through Committee without amendment and was read the third time. The money resolution in connexion with the Bill was also agreed to.

The Diseases of Animals Bill was considered on report and read the third time.

Balconies to Working-class Flats

In the House of Lords on July 15th the Housing Bill was considered on report.

The Earl of Dudley moved an amendment to clause 31 (Exchequer contributions towards provision of flats on sites of high value) to ensure that the approval of the Minister of Health should not be given to flats for the working-classes unless he was satisfied that each flat in a block exceeding three stories in height was provided with a balcony. He said that medical evidence showed that in the case of families living in the top stories of flats, infant children suffered considerably because their mothers were unable to take them out into the air and sunshine Architectural and technical research showed that the cost of erecting balconies on the high flats would come to very little. Since this matter was raised on the Committee stage of the Bill he had consulted the Minister of Health, with his medical and architectural experts. He understood that the Minister recognised the desirability of such balconies but that there were certain difficulties in the way of making this provision statutory. The Minister, however, was willing to give an assurance that he would emphasise the desirability of the provision of these balconies in a circular to the local authorities. Recognising the genuine sympathy of the Minister he (Lord Dudley) thought that that would meet the case he had in mind

Viscount Halifax, Secretary of State for War, said he could give the assurance which Lord Dudley desired. The Minister of Health would see to it that this matter was mentioned in the Circular which it was proposed to send to local authorities.

The amendment was withdrawn and the Bill passed through the report stage.

Health Services in Aden Protectorate

In the House of Lords on July 15th the Earl of Plymouth, replying to a question by Lord Lamington on the affairs in the Arden Protectorate, said that the system which already existed of training certain natives in the protectorate in elementary hygiene and health service was being extended. This training had resulted in the setting up of what might be termed native dispensaries which were necessarily of a somewhat elementary nature, but which were able to do valuable work. These dispensaries were supervised by the political officers.

Health Insurance Bill: Maternity Benefit Concession

In the House of Commons on Monday, July 15th, the National Health Insurance and Contributory Pensions Bill, as amended in Committee, was considered on Report.

On clause 1 (Amendment of Section 3 of Insurance Act with respect to free insurance period and extended insurance period),

Sir Kingsley Wood, Minister of Health, moved an amendment to provide maternity benefit to insured persons during their extended insurance period. He said that a general desire was expressed in the Committee stage for this concession. The House would appreciate his desire not to place a further charge on the funds of the approved societies who had already so willingly undertaken to bear their share of the considerable cost of the benefits made available under the Bill. Moreover, it was difficult to forecast with any precise accuracy the cost of this proposal, as it depended on so many uncertain factors, including the number of persons who would pass into the extended insurance period and the birth-rate prevailing among such persons. A close investigation had been made into the finance of the health insurance scheme with all these matters in mind, and particularly modifications had been introduced into the Bill in connexion with the setting up of the Unemployment Arrears Fund. As a result they had found a source from which the additional cost could be met—namely, the balance of the unclaimed stamps money, which was not under the Act required to be paid to the Central Fund. Therefore he (Sir Kingsley Wood) was able to meet the wishes of the House and at the same time not cast any further burden on the funds of the approved societies. He was very glad to be able to secure to insured persons in the extended period not only medical benefit and additional treatment benefits, but maternity benefit as well. (Cheers.)

The amendment was agreed to and four consequential amendments were made.

On the motion for the third reading of the Bill,

Sir Kingsley Wood said it was satisfactory to know that those who had elected as voluntary contributors to continue their insurance would not suffer any disadvantage from having taken that course. They would be able, on complying with the usual conditions, to obtain the benefits now given to unemployed persons in connexion with the continuation of insurance. He was also glad that a number of amendments had been made in this Bill which would facilitate the task of the consolidation of the Statutes respecting National Health Insurance. The Bill certainly secured to an insured person who had occasional periods of unemployment not exceeding 21 months in duration should not suffer any reduction whatever in benefits to which he or she might be entitled. His arrears would be completely excused and the benefit periods for a person would be treated in just the same way as if he had been in continuous employment. This would be a real and welcome benefit affecting some 5,000,000 insured persons. The Bill went further and provided for the still more unfortunate person who suffered from prolonged unemployment. Any person who had been insured for 10 years before becoming unemployed would be entitled to medical and maternity benefits and his old age and widows' and orphans' pension would be maintained unimpaired as long as his unemployment continued. It was all the more satisfactory that in making these changes the financial stability of national insurance would not be in any way jeopardised, and as far as approved societies were concerned, not only would they be of great value to those members who unhappily suffered from unemployment, but would result in a great simplification of the working of National Health Insurance.

The Bill was read the third time and passed.

◆

HOUSE OF COMMONS

WEDNESDAY, JULY 10TH

Meals for Necessitous Children

Mr. Cleary asked the Minister of Labour the approx-mate amount saved, firstly in Liverpool and secondly the country, by the action of the Unemployment Assistance Board in making deductions in respect of meals granted to necessitous children.—Lieut.-Colonel Muirhead, Parliamentary Secretary to the Ministry of Labour, replied : The Board inform me that no information s available as to the aggregate effect of taking into account ree meals provided at school to children in applicant's ouseholds. As the hon. Member was informed on uly 3rd, there are several classes of cases in which the Board ignore such meals. In the remaining cases in which meals are taken into account to a moderate extent, no onsideration of saving to the Exchequer arises.

Mr. Cleary : Is the hon. gentleman prepared to make an nquiry into this subject in view of the fact that the policy f the Unemployment Assistance Board is militating gainst the policy of the Board of Education which ncourages the granting of meals in industrial areas articularly ?

Lieut.-Colonel Muirhead : I will certainly consider it.

THURSDAY, JULY 11TH

Hospitals and the Lotteries Act

Lieut.-Colonel Acland Troyte asked the Home ecretary whether he could give any estimate of the mount of money which would be lost annually to hospitals s a result of the Betting and Lotteries Act ; and whether e proposed to bring in a Bill to amend this Act so as to low small lotteries to be held for the benefit of hospitals nd other recognised institutions.—Sir John Simon plied : I have no information which would enable me to ply to the first part of the question. As regards the cond part, the House considered, during the passage of he Betting and Lotteries Act, 1934, various proposals for galising lotteries in aid of hospitals and other charities ut rejected them.

Lieut.-Colonel Acland Troyte : Is the right hon. gen-eman aware that my local hospital has lost £700 or £800 year owing to this Act, and that it is going very much urther than it appeared the House intended to go ; and will he right hon. gentleman make further inquiries ?

Sir John Simon : My hon. friend will realise that very reful examination was given to this question by the House. must point out to him that as far as I know the Act 1934 did not make illegal any type of lottery which as previously legal.

Lieut.-Colonel Acland Troyte : Does the right. hon. ntleman realise the extent to which it is being applied ?

Viscountess Astor : Is it not the case that it has been ated that these lotteries do more harm than good to the ospitals in the year ?

Sir John Simon : It certainly must be borne in mind at assuming that efforts were made to finance hospitals this country by means of lotteries, it does not neces-rily follow that the existing sources out of which the ospitals receive help would continue to flow.

Sir Wilfrid Sugden : In view of the confused state the betting law, will the right hon. gentlemen consider e possibility of its codification ?

Mr. Paling : Since the passing of the Act has there en any evidence of any great demand for the restoration these lotteries ?

Sir John Simon indicated dissent.

Free Milk for Necessitous Children

Sir William Jenkins asked the President of the Board Education if he would give reasonable discretion to local ucation authorities to grant free meals or free milk to y child where it was within the definite knowledge of e authority that the economic conditions in the child's me were exceptional.

Mr. Thorne asked the President of the Board of Education the attitude of the Board to those local education authorities who were giving free meals or milk merely on the ground of poverty, where the family income was below a certain minimum.—Mr. Oliver Stanley replied : The attitude of the Board in the matter has been set out in a letter dated Nov. 14th, 1935, to the Secretary to the Association of Education Committees. In general, I should agree that the economic conditions of the homes are a factor to which full weight should be given in considering how much importance should be attached to any physical signs or educational symptoms which may be noted by the medical officer or the teacher.

Viscountess Astor : Is it not a fact that over 30 per cent. of the children attending elementary schools are either physically defective or in need of medical observation ? In view of that fact, will not my right hon. friend do all he can to bring in a policy to deal with free milk in schools ?—Mr. Stanley : If the noble lady really wants to know what the figures are perhaps she will put a question down. If she is only giving me information, I am obliged to her.

Maternity and Child Welfare

Mr. George Griffiths asked the Minister of Health the names of the maternity and child welfare authorities which made provision for home helps, and whether his sanction had been given or refused to any authority which had proposed to institute this service within the last two years.—Sir Kingsley Wood replied : There are 133 maternity and child welfare authorities, who according to my latest information have made provision for this service. I will send the hon. Member a list of these authorities, showing those to which sanction has been given within the last two years. There is no case within that period in which sanction has been refused to a proposal to institute this service.

Milk and the Germicide Process

Mr. Rickards asked the Minister of Health whether the new process of adding germicide to milk for destroying bacteria had been brought to his notice ; whether he would have the process tested and investigated ; and consider whether any modification of the Food and Drugs Adulteration Act would be required to permit of milk so treated being sold on a commercial scale.—Sir Kingsley Wood replied : I have recently been informed of a claim to the discovery of a new germicide for milk but I have no knowledge of its composition and no sample has been supplied to my Department. The addition of any germicide to milk would be contrary to the provisions of the Preservatives Regulations and the Food and Drugs (Adulteration) Act, and for the reasons set out in the report of the Departmental Committee on Preservatives in Food I could not contemplate any amendment of the law in this respect.

Brigadier Clifton Brown : In view of the report of the Milk Reorganisation Commission that the Food and Drugs Act should be amended in various particulars, will not my right hon. friend include this matter with other recommendations when this Act is reviewed ?

No further answer was given.

Committee on Nutrition : Welsh Medical Representative

Sir William Jenkins asked the Minister of Health whether he would appoint some medical expert from South Wales or Monmouthshire who had had experience of the depressed areas on the advisory committee who were now considering the question of national nutrition.—Sir Kingsley Wood replied : I have decided, in consultation with my right hon. friend the Secretary of State for Scotland, to appoint the Senior Medical Officer of the Welsh Board of Health to be a member of this Committee.

Beddington Sewage Scheme

Mr. Doran asked the Minister of Health if he was now in a position to give a statement regarding the progress of the Beddington sewage scheme, Croydon ; and if he could assure people resident in the Mitcham, Thornton Heath, and West Croydon districts that all necessary precautions had been taken taken by his department, in conjunction with the Croydon corporation, against a repetition of the insanitary conditions which were experienced in these areas in 1934.—Sir KINGSLEY WOOD replied: I am informed that a scheme for dealing with the whole of the sludge will be placed before the Council at their meeting this month. Any scheme put forward will be fully investigated by the Ministry before sanction is given. Interim measures have been taken to prevent nuisance.

Maternal and Infantile Mortality at Hebburn-on-Tyne

Mr. PEARSON asked the Minister of Health if he had considered the annual report of the Medical Officer of Health for Hebburn-on-Tyne, in which it was stated that the infantile mortality-rate had risen from 86 per 1000 live births last year to 108 this year, and that for every 116 babies born last year a mother died, the average being almost double that for the whole country; and, in view of the seriousness of the problem, will he hold an inquiry into the reasons for this high rate of maternal and infantile mortality.—Sir KINGSLEY WOOD replied: I have received this report and have arranged for one of the medical officers of the Department to visit the district and inquire into the relevant circumstances.

Coloured Population and Public Health in Cardiff

Captain ARTHUR EVANS asked the Minister of Health, if he would consider the Report of the survey of the conditions of the coloured and half-caste population domiciled in the city of Cardiff, conducted by a joint committee of the British Social Hygiene Council and the British Council of the Mercantile Marine, which had been sent to him; and if, in view of the health, employment, and social conditions found to be prevailing, he would take suitable action to remedy the matter.—Sir KINGSLEY WOOD replied: I do not find that I have yet received a copy of the Report to which my hon. friend refers, but if he will arrange for me to be supplied with one, I will gladly consider it, in so far as it refers to matters within the province of my Department.

Captain EVANS: When considering the report in question will my right hon. friend bear in mind the desirability of appointing a small Royal Commission, say of three persons, with wide terms of reference, to investigate all aspects of the difficult and complex problem of coloured people domiciled in Great Britain, especially in dock areas?

Sir KINGSLEY WOOD: That is a very wide question and probably outside my province, but I had better see the report first.

Lunacy and Mental Deficiency

Mr GUY asked the Minister of Health whether he would consider amending the lunacy laws with the object of providing differential treatment for mental deficiency.—Sir KINGSLEY WOOD replied: In England and Wales the Mental Deficiency Acts, 1913 to 1927, make express provision for the ascertainment and treatment of mental defectives, as distinct from persons dealt with under the Lunacy and Mental Treatment Acts, 1890 to 1930. I am not aware of circumstances necessitating action such as my hon. friend suggests.

Backwardness of African Natives

Sir E. GRAHAM-LITTLE asked the Secretary of State for the Colonies whether his Department was now in a position to recommend a grant for a scientific investigation into the causes of physical and mental backwardness in the natives of Kenya Colony, an investigation demanded on repeated occasions by scientific bodies in Kenya and in this country and supported by his excellency the Governor of Kenya Colony.—Mr. M. MACDONALD, Secretary, replied: No, Sir, there are no funds at the disposal of my Department from which any grant for such purpose could be made. The importance of inquiry into the mental and physical development of African natives is recognised. But before deciding what steps should be taken I propose to await the issue of the general investigation which is to be conducted by the African Research Survey, under Sir Malcolm Hailey. I understand that this survey will take the form of a review of African problems, generally and that it will indicate the extent of existing knowledge concerning those problems and the steps to be taken to supply any deficiencies in that knowledge. The inquiry to which the hon. Member refers is only one part of the general survey, and the necessity for any special investigation of it must be considered in the light of its relation to other factors. It is in regard to the inter-relation of African problems and relevant factors that the general investigation will, it is hoped, be of special value in determining the course of future research.

Advertisements of Patent Medicines

Mr. HALL-CAINE asked the Minister of Health whether arising out of the recent deputation received by him on the subject he proposed to introduce legislation controlling the advertising in this country of patent medicines.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend is not at present in a position to make any statement on this subject.

Atmospheric Pollution

Mr. THOMAS WILLIAMS asked the Minister of Health whether, in order to secure a cleaner atmosphere and the consequent improvement in the public health, he would recommend to the notice of other local authorities the action of the city of Manchester, which was now carrying out tests of smokeless fuels in its town hall over a period of 12 months; and what had been the Ministry's own experience of smokeless fuel.—Mr. SHAKESPEARE replied: The tests at Manchester have been only recently commenced. The results of the tests will no doubt in due course be available for other authorities. My right hon. friend is informed by the First Commissioner of Works that smokeless fuel has been found satisfactory for use in open grates, but the cost is at the present time greater than that of ordinary house coal, after allowing for relative efficiency.

Injured Workmen and Supply of Surgical Appliances, &c.

Mr. TINKER asked the Home Secretary if his attention had been drawn to the large number of cases of injured workmen who had to get surgical appliances, artificial legs, arms, &c., to assist them to follow their employment; that there was nothing in the Workmen's Compensation Act to cover the cost; and if he will consider amending it so that all such cases shall be met by payment of the cost incurred.—Captain WALLACE, Under-Secretary Home Office, replied: No recent representations to my Department on this subject can be traced, but if the honourable Member will send me particulars of any cases of workmen being unable to obtain necessary appliances without hardship owing to having to defray the cost, I will look into the matter and consult, if necessary, my right hon. friend, the Minister of Health.

Small-pox and Compulsory Vaccination

Mr. GROVES asked the Minister of Health when vaccination against small-pox became obligatory in this country, and what was the effect.—Sir KINGSLEY WOOD replied: vaccination against small-pox for new-born children first became obligatory in this country in 1853. While it is not easy precisely to assign particular effects to this measure, its immediate practical effect may perhaps be gauged from the fact that whereas in the six years 1847 to 1852 the average annual mortality from small-pox per million living persons was 326, the average figure for the six years 1854 to 1859 was 187.

Herbalists

Sir ERNEST GRAHAM-LITTLE asked the Home Secretary whether he was aware that the Statute 34 and 35 Henry VIII., c.8, making provision whereby persons having a certain knowledge of herbs and roots could be privileged to engage in some branches of medical practice was still in force, and that a body calling itself the College of Botanic Therapy claimed under that charter to be privileged to issue diplomas conferring legal status differing from the status of herbalists who had no such diploma; and what steps he proposed to take in the matter.—Sir KINGSLEY WOOD, Minister of Health, replied: I am aware of the statutory provision referred to. I was not previously aware of the claim said to be made by the College of Botanic Therapy and I do not know on what it is based, but I do not feel called on to take any steps in the matter.

TUESDAY, JULY 16TH

Medical Inspection in Scottish Prisons

Mr. LEONARD asked the Secretary of State for Scotland if he had instructed governors and medical officers of Scottish prisons jointly to inspect every part of the prison establishment and to record the result of this inspection in their respective journals; and, if so, would he given the dates of such inspections in the last 12 months in Barlinnie prison recorded in the journals referred to.—Sir GODFREY COLLINS replied: The Prisons (Scotland) Rules provide that the governor and medical officer of each prison shall jointly inspect every part of the prison establishment in the last month of every quarter and that the results of these inspections shall be recorded by the medical officer in his journal. Owing to the length of time necessary to make a thorough inspection of the whole establishment at Barlinnie Prison, it has not always been practicable for the governor and medical officer to make joint inspections, and steps are being taken in the course of the comprehensive revision of the Prison Rules, which is now in progress, to amend the rules dealing with this matter. The dates of the inspections carried out at Barlinnie Prison in the last 12 months were as follows, viz., governor's inspections, Oct. 1st, 1934, Dec. 24th, 1934, March 29th, 1935, and June 18th, 1935. Medical officer's inspections, recorded in the medical officer's journal: Sept. 28th, 1934, Dec. 21st, 1934, March 29th, 1935, and June 21st, 1935.

Mr. LEONARD asked the Secretary of State for Scotland if he was aware that prisoners in Barlinnie prison, ordered to their cell beds as sick, were forced to parade at the prison surgery the following morning along with the prisoners reporting sick; that influenza patients had had to conform to this practice; and would he take steps to ensure that prisoners ordered to bed as sick would be visited in their cells by the medical officer before being called to parade with the ordinary sick.—Sir GODFREY COLLINS replied: Prisoners in Barlinnie who have been ordered to bed because of ailment are not paraded at the surgery on the following morning except when the ailment is a minor one. If the prisoner complains of feeling unwell he is kept in bed until examined by the medical officer. Where influenza has been diagnosed the prisoner is not paraded at the surgery, but is either admitted to the prison hospital or kept in bed in his cell until the medical officer certifies him as fit to get up. The practice does not seem to call for any alteration.

MEDICAL NEWS

University of Cambridge

On June 25th the following degrees were conferred:—

M.D.—G. G. Penman, G. F. Abercrombie, *E. A. Trim, and A. C. Crooke.

M.B., B.Chir.—John Cann, J. H. Shakespeare, John Collinson, Norton Stevens, and E. C. Sugden.

M.B.—R. D. Roper, N. G. Hulbert, P. H. L. Playfair, Benjamin Holden, and G. O. A. Briggs.

B.Chir.—J. F. Dow, R. E. Rodgers, H. S. Wigfield, *Wilfrid Warren, D. A. Smith, and R. T. Gabb.

*By proxy.

University of London

At recent examinations the following candidates were successful:—

D.P.H.

V. F. Anderson, J. H. Blakelock, Hilda L. Byett, Alan Carling, H. S. Davies, David Erskine, W. G. Evans, Mohomed Farooq, O. M. Francis, H. A. Gilkes, J. V. Hurford, Muriel V. Joscelyne, J. T. R. Lewis, Edyth L. Morris, Vaithianather Nadarajah, N. C. Parfit, L. M. Ram, C. J. Sanderson, Hubert Smith, Thomas Standring, E. W. Taylor, V. T. Vagh, J. D. V. Wijeyaratne, W. W. Wildman, R. A. Wilson, and E. D. B. Wolfe.

William Julius Mickle Fellowship.—This fellowship is awarded to the graduate of the university who has done most to advance medical art or science during the last five years. Application should be made to the principal of the university not later than Oct. 1st.

Rogers Prize.—This essay prize will be offered for award in 1936 and is open to all registered medical practitioners. The subject which has been chosen is the natural history of peptic ulcers and essays should reach the vice-chancellor by April 30th. Further particulars may be had from the academic registrar at the University, South Kensington, London, S.W.

University of Aberdeen

On July 10th the following degrees and diploma were conferred:—

M.D.—*F. W. Gordon, *J. S. Robertson, E. R. Sorley (in absentia).

*With commendation.

M.B., Ch.B.—A. J. Slessor (second-class honours), R. A. Barraclough, R. P. M. Brown, W. J. Cameron, A. B. Christie, Dorothy M. Chrystall, Archibald Crerar, J. F. Croll, A. R. R. Cumming, G. I. Davidson, J. J. R. Duthie, Norman Gill, W. T. Gordon, Margaret M'N. Little, Christopher MacDonald, J. S. Mackay, Helen C. S. MacLean, A. D. Morgan, B. M. Nicol, F. J. A. Norris, C. J. Silver, D. F. Smith, T. A. Smith, J. L. Stephen, D. O. Stevenson, R. M'P. Stewart, J. L. Taylor, J. M. Thomson, A. A. White, and W. J. R. Wyness.

D.P.H.—J. G. H. Davidson.

Royal College of Surgeons of England

A quarterly meeting of the council was held on July 11th with Sir Holburt Waring, the president, in the chair. Sir Cuthbert Wallace was elected president for the ensuing year, and Mr. A. H. Burgess and Sir Charles Gordon-Watson were elected vice-presidents. Mr. W. Sampson Handley was appointed a member of the executive committee of the Imperial Cancer Research Fund. Sir Frank Colyer, was reappointed hon. curator of the odontological collection, and Mr. C. J. S. Thompson, hon. curator of the historical collection. The Hallett prize, given in connexion with the primary fellowship examination, was awarded to John Philip Bentley of King's College, London.

The following professors, lecturers, and demonstrators were appointed for the ensuing year: Hunterian Professors: Mr. A. F. MacCallan, the surgery and pathology of trachomatous conjunctivitis; Mr. F. H. Bentley, wound healing by tissue culture methods; Mr. A. M. Boyd, the peripheral circulation in occlusive and spasmodic diseases of the vessels; Mr. Arthur Bulleid, dental sepsis as a factor affecting medical and surgical procedures; Mr. H. Osmond Clarke, injuries of the carpal bones; Mr. John Gilmour, adolescent deformities of the acetabulum; Mr. G. C. Knight, intestinal strangulation; Mr. G. A. Mason, extirpation of the lung; Mr. Reginald Payne, pyogenic infections of the parotid; Mr. G. F. Rowbotham, a series of tumours of the skull; Mr. E. P. Stibbe, the anatomy and surgery of the subtentorial angle; and Dr. E. W. Twining, a radiographic study of the third ventricle. *Arris and Gale Lecturer:* Dr. John Beattie, temperature regulation. *Erasmus Wilson Lecturers:* Mr. C. E. Shattock and Mr. C. P. G. Wakeley, demonstrations on pathology; and Dr. L. W. Proger, four demonstrations on pathology. *Arnott Demonstrator:* Dr. A. J. Cave, demonstrations on the contents of the museum.

Dr. Arthur Maitland-Jones was elected an examiner for the Special Diploma in Child Health. A diploma of fellowship was granted to E. S. Allin, and a diploma of membership was granted to H. B. Hunt.

Licences and diplomas were granted jointly with the Royal College of Physicians, as follows:—

L.D.S.—R. H. C. Ballauff, E. A. Beach, R. A. Beck, M. R. Blair, E. B. Briault, Harry Caldwell, C. R. Collis, W. G. C. Dickson, D. J. Dymond, W. E. Earle, F. M. Eisenstaedt, N. L. Forrester, D. W. Friendship, P. F. B. Gillett, D. A. Godfrey, D. E. Holdway, Harry Jackson, P. F. James, O. C. Jenkins, K. A. Keith, W. C. J. King, G. C. H. Kramer, W. F. Leuner, E. B. Lloyd, S. R. Luton, A. J. May, W. J. R. C. Morgan, Edgar Nelson, A. G. Richmond, J. F. Russell, J. F. M. Sampson, E. R. L. Shrimpton, E. H. F. Webb, D. J. Wigginton, and T. J. Wood.

D.P.H.—A. A. Cunningham, W. L. Devlin, H. A. Ferguson

W. P. Greenwood, E. T. Jones, Behari Lal, F. J. Murphy, T. H. Parkman, S. C. St. G. C. Parry, and R. W. Tannahill.

D.T.M. & H.—A. G. Biggam, E. M. Clark, H. J. Curran, O. E. Fisher, I. D. Gebbie, L. N. Goel, J. O. Gordon, G. M. Graham, G. T. Hindley, J. H. Hudson, D. C. Lahiri, J. S. McNair, P. D. Mohandirange, Théodora Papafigou, E. G. Wilkins, F. J. Wright, and L. P. Younglao.

D.P.M.—*Karl Biden-Steele, S. R. Bray, A. C. Dalzell,* C. C. Edwards, R. E. Hemphill, Margaret N. Jackson, D. E. Jones, T. B. Jones, W. S. Maclay, Bernard Matheson, and I. A. Senanayeke.

D.L.O.—J. W. Gerrie, Kennedy Hunter, R. V. Rao, and Robert Williamson.

University of St. Andrews

Dr. A. R. Moodie has been appointed lecturer in ophthalmology and clinical ophthalmology. Dr. A. M. MacGillivray, lecturer in clinical ophthalmology in the Medical School, Dundee, and Lieutenant-Colonel T. J. Mitchell, assistant in anatomy in the United College, St. Andrews.

University of Dublin

At recent examinations in the School of Physic, Trinity College, the following candidates were successful :—

FINAL EXAMINATION FOR M.B., B.CH., AND B.A.O.

Therapeutics and Pathology.—*E. W. L. Thompson, *J. H. A. Jewell, *J. A. Strong, *J. G. Steinbock, M. C. Wood, Max Levy, Sterling Tomlinson, J. M'C. Caldwell, Stella M. Coen, B. G. Kearon, D. J. H. Douglas, D. S. Toole, E. M'G. Cochrane, H. F. T. MacFetridge, C. H. Blackham, Maureen N. S. Mason, P. J. Mullaney, W. D. Chesney, H. J. Walker, W. E. Counihan, E. G. Fox, and Rebecca M. R. Pike.

Medicine.—B. E. O'Brien, D. P. Burkitt, G. J. Dixon, Murie E. Wallace, Maureen C. E. Gore-Grimes, J. C. Gaffney, H. J. Anderson, H. C. Bourke, Harold Pringle, Emanuel Cowan, A. E. Fannin, J. R. Kellett, N. G. Farrell, William Charney, B. M. O'Sullivan, D. J. Hayes, S. B. Sachs, J. R. M'Elroy, R. L. Oakes, J. C. Roux, J. A. Hamilton, F. J. C. Loughran, F. T. P. Bergin, G. W. M. Elliott, R. H. Pratt, R. A. Bond, P. X. O'Dwyer, and A. F. H. Keatinge.

D. G. Walker and P. St. G. Robinson.

Surgery.—J. N. P. Moore, D. G. Walker, H. J. Anderson, Muriel E. Wallace, Harold Pringle, B. E. O'Brien, G. J. Dixon, J. R. Kellett, D. P. Burkitt, Maureen C. E. Gore-Grimes, H. G. Ellerker, L. W. M'Caughey, Maurice Marmelstein, R. H. Pratt, A. D. Egan, R. H. Simon, J. R. M'Elroy, William Charney, and N. G. Farrell.

Midwifery.—S. J. H. Douglas, G. C. Retz, John M'Quillan, W. S. M'Bride, Benjamin Rogol, D. P. Harris, Neville Jackson, P. L. van Aardt, G. S. Caithness, and Eithne M. O'Connell.

D.P.H.

Part II.—D. B. Bradshaw, G. A. Miller, J. K. Lavery, and T. J. O'Sullivan.

DIPLOMA IN GYNÆCOLOGY AND OBSTETRICS

M. J. Eakin, C. F. Marks, Chan Ping In, and H. A. Shawarby.

*Passed on high marks.

National University of Ireland

At recent examinations the following candidates were successful :—

M.D.

J. P. Sheehan.

M.B., B.CH., AND B.A.O.

J. G. Barrett, John Breen, Brendan Buckley, James Burke, Jeremiah Cogan, J. P. Corcoran, R. A. Coughlan, D. C. Lawton, J. N. McCarthy, E. M. Newman, John O'Herlihy, and Thomas O'Neill.

Part I.—Vincent Bennett, P. J. Kelleher, Cornelius McGrath, Samuel Nathan, V. J. O'Sullivan, and William O'Sullivan.

Part II.—Michael Kirwan.

D.P.H.

Part I.—Elizabeth J. H. Philpott (née Harris) and R. G. Cross (with second-class honours); D. F. Burke, T. G. A. Carroll, R. A. Good, M. F. Kelleher, M. J. Kennefick, and J. P. O'Leary.

Mr. Robert Dwyer Joyce, has been appointed to the chair of ophthalmology at University College, Dublin.

Mr. Joyce was born in Dublin in 1875, and received his medical education at the universities of Dublin, Vienna, and Berlin. He qualified M.R.C.S. in 1895, and in 1899 obtained the fellowship of the Royal College of Surgeons in Ireland. He was appointed ophthalmological surgeon to the Richmond Hospital, Dublin, and was later appointed to the same position at the Mater Misericordiæ Hospital, which he still holds. He also acts as examiner in ophthalmology for the Royal College of Surgeons in Ireland. His contributions to medical journals include papers on the topography of the facial nerve in its relation to mastoid operations, and on detachment of the choroid.

Dr. D. J. Coffey, pro-vice-chancellor of the University, and president of University College, Dublin, was reappointed representative of the University on the General Medical Council for a further period of three years.

At recent examinations for the B.D.S. degree, Percy Greinson and N. L. Newman were successful.

Queen's University, Belfast

At recent examinations the following candidates were successful :—

M.D.

F. J. Booth and D. H. Smyth (with gold medals), D. H. Smyth (with commendation), Winifred E. Hadden, J. M. Houston, S. W. T. Lee, D. W. Macartney, D. M. Morrison, R. W. Mussen, J. A. Price, Lilian V. Reilly, J. M. C. Speer, Gerald Townsley, and H. B. C. Wallace.

M.B., B.CH., AND B.A.O.

W. M. Brennen, T. D. Carson, G. A. Craig, C. H. Cullen, J. S. Matthews, and J. G. Pyper (with second-class honours), S. J. Allen, Rosetta C. Barker, J. F. Beck, J. W. Burns, C. F. Campbell, J. T. Carson, T. P. Diamond, Mary R. M. Donnelly, K. I. H. Henry, James Houston, R. A. Johnston, M. C. Kelly, Martha L. Kennedy, H. J. Knox, P. A. Lee, S. E. C. Lyons, K. C. M'Keown, T. A. MacLynn, R. W. M'Namara, J. N. Macartney, H. G. Magill, N. S. Martin, J. L. E. Millen, J. K. Moffett, R. A. Monteith, R. S. Nixon, Charles Reid, J. N. W. Ritchie, J. G. Rountree, C. V. P. Ryall, A. H. Scott, R. H. F. Smith, W. M. Stewart, A. W. Thompson, Anna V. Thompson, and N. J. W. Thompson.

On July 13th, the hon. degree of LL.D. was conferred on Thomas Gillman Moorhead, M.D., regius professor of physic, Trinity College, Dublin ; the hon. degree of D.Sc. on Thomas Carnwath, M.B., senior medical officer, Ministry of Health ; and Major-General William Porter Macarthur, deputy director-general Army Medical Services.

The following degrees were also conferred :—

M.D.—F. J. Booth, H. G. Calwell, Winifred E. Hadden, J. M. Houston, S. W. T. Lee, D. W. Macartney, D. McV. Morrison, R. W. Mussen, J. A. Price, Lilian V. Reilly, D. H. Smyth, J. M. C. Speer, G. Townsley, and H. B. C. Wallace.

University of Sheffield

At a meeting of the university council held on July 12th the resignation of Prof. M. H. Phillips of the chair of obstetrics and gynæcology was received. The following appointments were made :—

Dr. G. L. Roberts, to the chair of dental surgery; Mr. John Chisholm, to the chair of obstetrics and gynæcology ; Dr. W. J. Wellwood Ferguson, hon. lecturer in ophthalmology, in succession to Dr. P. J. Hay, who has resigned ; Dr. J. MacD. Croll, lecturer in bacteriology; and Dr. Edward S. Duthie, demonstrator in pathology.

Dr. Roberts graduated M.B. with second-class honours at the University of Liverpool in 1927, and in the next year he obtained the degree of B.D.S. with first-class honours. He held the position of tutor of clinical dental surgery at the University of Leeds, and was hon. demonstrator to the Leeds Dental Hospital. He returned to Liverpool as demonstrator of clinical dental surgery of its dental school, but later went to Birmingham to take up his present post as tutor of dental clinical subjects at the dental school of Birmingham University.

Mr. Chisholm was born in Inverness in 1883, and was educated at Inverness Royal Academy and Edinburgh University, where he graduated M.B. in 1905. After holding resident appointments at St. Mary's Hospital, Manchester, and the Jessop Hospital for Women, Sheffield, he joined the honorary staff of the Jessop Hospital as assistant surgeon and surgeon in charge of the venereal diseases clinic, and is now a member of the senior staff. He is hon. consulting gynæcological surgeon to the Royal Hospital, Sheffield, and lecturer in obstetrics and gynæcology in the University. During the war he held the rank of captain in the R.A.M.C. He became a fellow of the Royal College of Surgeons of Edinburgh in 1920.

Mr. H. C. Malleson, of Guy's Hospital, was appointed an external examiner for the Ph.D. degree.

University of Durham

Dr. E. Farquhar Murray has been appointed professor of midwifery and gynæcology in succession to Prof. R. P. Ranken Lyle.

Dr. Murray is a son of the late Mr. Robert Murray, of Dundee, and a brother of the late Prof. Leith Murray. He received his medical education at St. Andrews, St. Bartholomew's Hospital, Paris, Dublin, and Munich. He qualified M.B. with honours at St. Andrews in 1908 and M.D. in 1911, afterwards going to London, where he held resident appointments at the Chelsea Hospital for Women and Queen Charlotte's Hospital. At the outbreak of war he joined the R.N.V.R. and served as a surgeon-lieutenant, being mentioned in dispatches for distinguished services. In 1918 he obtained the fellowship of the Royal College of Surgeons of England, and after demobilisation was appointed to the staff of the Newcastle Maternity Hospital as assistant. In 1920 he joined the staff of the Royal Victoria Infirmary where he later became hon. gynæcologist, and in the same year he was appointed lecturer in midwifery and gynæcology at the University of Durham College of Medicine. He is a foundation member and fellow of the British College of Obstetrics and Gynæcology and has published papers on radium in treatment of cancer of cervix and menorrhagia, puerperal sepsis, and investigations of tubal abnormalities.

Dr. W. Fletcher Shaw, professor of clinical obstetrics nd gynæcology in the Victoria University of Manchester, as been elected an honorary fellow of the American ynæcological Society.

Velsh National School of Medicine

Dr. L. H. Howells has been appointed demonstrator n the department of materia medica and pharmacology, nd Dr. J. D. Spillane, junior assistant in the medical unit.

Egyptian University, Cairo

Dr. F. H. Smirk has been appointed to the chair of pharmacology in the University. Dr. Smirk, who graduated at Manchester in 1925, at present holds a Beit memorial fellowship and is assistant to the pharmacological department of University College Hospital.

St. Mary's Hospital Medical School

The annual dinner of past and present students of this school will be held at Claridge's Restaurant on Saturday, Sept. 28th, at 7.30 P.M. Mr. Duncan C. L. Fitzwilliam will be in the chair. The hon. secretary is Dr. A. Hope Gosse.

The post-graduate course, which is open to all medical practitioners without fee, will take place on Sept. 27th, 28th, and 29th.

Society for Relief of Widows and Orphans of Medical Men

The quarterly meeting of the directors of this Society was held on July 3rd with Dr. R. A. Young in the chair. One new member was elected and the deaths of three members including Dr. W. Culver James, senior vice-president of the Society were reported. Dr. James was elected a member in 1882 and always took a great interest in the work of the Society. The sum of £2258 was voted for the payment of the half-yearly grants to the 54 widows and 11 orphans in receipt of relief. Three widows of deceased members applied for relief; one who was 71 years of age was voted a yearly grant of £75 and the other two, a yearly grant of £60. Relief is granted only to the necessitous widows and orphans of deceased members. Membership of the Society is open to registered medical men, who at the time of their election are resident within a 20-mile radius of Charing Cross. Full particulars may be obtained from the secretary 11, Chandos Street, London, W.1.

British College of Obstetricians and Gynæcologists

At the quarterly meeting of the council held on July 13th Sir Ewen Maclean was elected president. Dr. H. Russell Andrews and Dr. Bethel Solomons were elected vice-presidents; Mr. Eardley Holland was re-elected hon. treasurer; Sir Gomyns Berkeley hon. appeal treasurer; Prof. Fletcher Shaw hon. secretary; Mr. Frederick Roques hon. librarian.

The following were elected to the membership:—

H. G. E. Arthure (London), Narendranath Basu (Calcutta), J. R. S. G. Beard (Adelaide), Bernard Berger (Bloemfontein), James Black (Johannesburg), Margaret G. Bott (Nottingham), Joyn H. Boyd (New York), R. B. Charlton (Brisbane), G. A. Cook (Melbourne), W. G. Cosbie (Toronto), A. J. Cunningham (New South Wales), Constance E. D'Arcy (Sydney), G. A. Davies (Sheffield), L. L. Davey (Adelaide), H. D. De Sa (Bombay), K. C. Donovan (Sydney), M. H. Elliot-Smith (Brisbane), Tom Farranbridge (Sydney), H. M. Fisher (Toorak), G. P. Fitzgerald (Dunedin), M. B. Frazer and R. I. Furber (Sydney), F. J. Hayden, W. I. Hayes and A. M. Hill (Melbourne), A. F. Hobson (Sydney), J. S. Hovell (Khartoum), T. D. Hughes (Sydney), H. S. Jacobs (Melbourne), J. Jhirad (Bombay), J. L. Jona (Melbourne), Alice M. Kenny (London), H. M. Lazarus (Madras), D. M. Low (Toronto), G. B. Lowe (New South Wales), H. I. McClure (Belfast), R. E. Magarey (Adelaide), B. T. Mayes (Brisbane), A. A. Moon and E. L. Newman (Sydney), L. B. Patrick (Sheffield), Hemendranarayan Ray (Calcutta), T. G. Robinson (Epsom), W. D. Saltau (Melbourne), Ida B. Saunders (Sydney), J. A. H. Sherwin (Melbourne), George Simpson (Victoria), T. H. Small (New South Wales), G. R. Sparrow (Toronto), G. R. Stoneham (New Zealand), Jane B. Stubbs (Manchester), W. E. C. Thomas (Ashton-under-Lyne), R. S. Townsend (Lucknow), H. B. Van Wyck (Toronto), Ramsay Warden (Melbourne), James Waterman (Port of Spain), Keith Vartan (London), and H. B. Williams (Sydney).

The following were admitted by the president:—

Fellows.—*L. C. Conn (Edmonton, Alberta), Amy M. Fleming and V. J. F. Lack (London), *W. C. Spackman (Bombay), and Leslie Williams (London).

Members.—M. D. Black (Glasgow), *Ebenezer Maduram (Madras), and Joyce Morgan (London).

* In absentia.

University of Manchester

Messrs. Boots Pure Drug Company, Limited, have made a grant of £300 per annum for three years for the provision of scholarships or technical assistance in the department of clinical investigations and research.

The following appointments are announced: Dr. Norman Kletz, lecturer in clinical medicine; Dr. William Brockbank, lecturer in medicine for dental surgery; Dr. D. H. Mackay and Dr. E. L. Patterson, demonstrators in anatomy; Dr. C. S. D. Don, demonstrator in systematic medicine; and Dr. Walter Schlapp, tutor and secretary to the faculty of medicine.

Leverhulme Research Fellowships

Leverhulme research fellowships have been awarded to Dr. D. B. Blacklock, professor of tropical medicine in the University of Liverpool; Dr. M. G. Blacklock, curator of the museum, Liverpool School of Tropical Medicine.

A grant in aid of research has been made to Dr. J. W. W. Stephens, F.R.S., emeritus professor of tropical medicine in the University of Liverpool. Application forms and further information may be obtained from the secretary, Leverhulme Research Fellowships, Union House, St. Martins-le-Grand, London, E.C.1.

The International Congress on Life Assurance Medicine

This congress meets in London next week, under the presidency of Sir Walter Langdon-Brown, at the offices of the Prudential Assurance Company, Holborn Bars, E.C. The meetings begin on Tuesday, and particulars may be had from the hon. secretary, Dr. Otto May.

In connexion with the congress an exhibition dealing with health service and life assurance, organised by Dr. Neustatter, of Berlin, is being held at the Prudential offices. Any medical men interested in the subject will be welcome on Tuesday, July 23rd, from 10 A.M. to 5 P.M., upon presentation of their visiting card.

London Hospital

Presenting his twenty-fifth annual report as dean of the medical college on July 11th, Prof. William Wright spoke of the additions of the last quarter of a century, including a dental school a clinical theatre, a cardiac institute, a residents' hostel, and a students' hostel. Seven new separate departments had been created, and six professorial chairs; funds of upwards of £100,000 had been accumulated for the advancement of medical research; ten members of the staff had been elected fellows of the Royal Society; while 1800 students had obtained a first medical qualification, and 300 a second or higher qualification such as F.R.C.S. or M.R.C.P. In reviewing the year, Prof. Wright mentioned the appointment of Dr. A. Burrows as assistant physician in the skin department, and Dr. J. R. Marrack to the new chair in chemical pathology. The various departments of clinical pathology have been combined under the directorship of Dr. P. N. Panton, and a neurological department has been established under Dr. George Riddoch and Dr. W. Russell Brain. Dr. J. Davidson and Dr. N. M. Goodman have been appointed lecturers in forensic medicine and public health respectively, while Dr. S. P. Meadows, Mr. H. E. Harding, and Mr. H. S. Morton have joined the staff as first assistants in the neurological, surgical, and obstetric departments. Dr. A. E. Clark-Kennedy has accepted the newly constituted office of sub-dean. The students' hostel, Prof. Wright reported, has admirably fulfilled its purpose, but unfortunately still carries a debt of £15,000. As for the entry of students, it was higher last year than at any time since 1918–19.

Presenting the prizes to the students, Mr. John Masefield, O.M., the Poet Laureate, expressed his distaste for the phrase "a healthy mind in a healthy body." "We have gone far beyond such things in these days," he said. "I feel that what both the writers and the men of science want is to have a delightful and a delighted mind in a delighted and delightful body." This goal would be brought nearer, he felt, if the direction of affairs were entrusted more to scientists and less to the haphazard demagogue. Sir William Goschen proposed a vote of thanks to Mr. Masefield, and this was seconded by Mr. Eardley Holland.

University of Oxford

It is announced that Lord Nuffield's gift for the equipment of the new institute of medical research (described in our issue of May 25th) will be £16,000. As already stated, Lord Nuffield has also made the Radcliffe Observatory building, and surrounding land, available for medical research.

General Board of Control for Scotland

Dr. Kate Fraser has been appointed commissioner of the General Board of Control for Scotland in place of Dr. H. C. Marr, who is retiring. Dr. Fraser holds at present the position of departmental commissioner under the Board.

Naval Medical Compassionate Fund

At the quarterly meeting of the directors of this fund, held on July 12th, with Surgeon Vice-Admiral R. W. B. Hall, medical director-general of the Navy, in the chair, the sum of £70 was distributed to applicants.

Medical Society of Individual Psychology

At the annual general meeting of this society on July 11th the following were elected officers and members of committee for next session: chairman, Dr. M. Bevan-Brown; vice-chairman, Sir Walter Langdon-Brown; treasurer, Dr. H. C. Squires; editor (if available), Dr. J. C. Young; secretary, Dr. Alexander Baldie; members of committee, Dr. Beattie, Dr. Taylor, Dr. Joyce Partridge, and Dr. Woodcock.

Imperial Social Hygiene Congress

The dinner given by the British Social Hygiene Council at the May Fair Hotel on July 11th celebrated the success of the seventh Imperial Social Hygiene Congress (reported on another page). Proposing the toast of Health and Education in the Empire, Prof. Winifred Cullis spoke particularly of the council's efforts to spread the teaching of biology and to apply it to the problems of life. The teaching of science would not make people perfect; biologists were not perfect themselves. But Prof. Cullis believed that it was a basis on which a better and fuller life could be built—provided always there was a conscience, and spiritual values, in the background. Replying to the toast, Dr. Arthur MacNalty, chief medical officer of the Ministry of Health and the Board of Education, referred to the international and imperial implications of public health work and of the Ministry's keen coöperation with the League of Nations Health Organisation in combating disease throughout the world. He paid a tribute to Mrs. Neville-Rolfe, secretary-general of the council, for her undiscouragable spirit in forwarding the work. Sir Francis Fremantle briefly proposed the Guests, guiding his hearers skilfully through posses of distinguished representatives of ministries and public health services. Sir Bede Clifford, governor of the Bahamas, in responding, regretted that half the Empire should not know where the other half was, and welcomed the Imperial Congress as a means of exchanging information and ideas. The Colonial Empire, he said, would hardly exist to-day but for the labours of medical men like Sir Patrick Manson, and their successors were doing invaluable work and making observations which ought to be better known. As an example of a small but possibly useful fact he mentioned that it had recently been noticed in the Bahamas that pellagra increased in years when hurricanes had destroyed the citrus fruits. In conclusion, Sir Bede referred to some of the problems of quarantine arising in an island situated only 200 miles from the American coast and linked with it by daily air services. Miss Florence Horsbrugh, M.P., also spoke of the value of the congress in informing public opinion. As a representative of Great Britain at Geneva she had learnt the necessity of the public understanding something of the problems that mattered most to mankind. There was far more talk about road accidents, for instance, than about health or housing. Replying to his health, proposed by Lieut.-Colonel Sandeman Allen, M.P., Sir Basil Blackett, the president, said that the council spread its net wide and was much in earnest. He recommended Government departments to do whatever Mrs. Neville-Rolfe told them.

Caledonian Medical Society

The annual dinner of this society was held at Bamburgh on June 28th under the presidency of Dr. James McDonald, of Belford, Northumberland.

Royal Hospital for Incurables, Putney

The Duchess of York will visit this institution on July 24th to open a new nurses' home which has been erected at a cost of £25,000. She will receive purses towards meeting this extra expenditure.

Warde-Aldham Hospital, South Elmsall

Lord Moynihan has opened a new X ray department and massage and theatre block at this hospital, which exists chiefly for the benefit of miners.

Western General Hospital, Edinburgh

Preliminary plans for the modernisation of this institution—one of the chain now run by the city—at an estimated cost of £120,000 are being considered. The nurses at present live in a block in the hospital, but it is proposed to build a new home a short distance away where they can live in pleasant surroundings.

Appointments

BENN, E. C., M.B. Liverp., has been appointed Medical Superintendent of the Leeds City Hospitals, Seacroft.

BOLAND, E. R., F.R.C.P. Lond., D.P.H., Assistant Physician to the Hospital of St. John and St. Elizabeth, London.

DOUGLAS, J. B., M.B. St. And., D.M.R.E., Radiologist to the Bethlem Royal Hospital, London.

GILPIN, ARCHIBALD, M.D., M.R.C.P. Lond., Assistant Physician to King College Hospital.

HAWKSLEY, J. C., M.D., M.R.C.P. Lond., Hon. Assistant Physician to University College Hospital.

HAYES, E. D. T., M.D. Dub., D.P.M., medical superintendent at the Northampton County Mental Hospital.

HERON, J. P., M.B., F.R.C.S. Edin., Resident Medical and Surgical Officer and Registrar at the Royal Albert Edward Infirmary, Wigan.

HOYLE, J. CLIFFORD, M.D., M.R.C.P. Lond., Assistant Physician to the Hospital for Consumption, Brompton.

JOHNSON, WILLIAM, M.D., F.R.C.P. Lond., Hon. Physician to the Royal Liverpool Children's Hospital.

MUSHIN, WOOLF, M.B. Lond., Hon. Assistant Anæsthetist at the Central London Throat, Nose, and Ear Hospital.

PEEL, J. H., B.M. Oxon., F.R.C.S. Eng., M.C.O.G., Registrar to the Samaritan Free Hospital for Women, London.

PLAYFAIR, PATRICK, M.B. Camb., F.R.C.S. Eng., Registrar at Queen Charlotte's Maternity Hospital, London.

PLUMMER, N. S., M.D., M.R.C.P. Lond., Assistant Physician to the Charing Cross Hospital.

RICH, W. M., L.R.C.P. Lond., Resident Medical Officer at the Keighley and District Victoria Hospital.

TAYLOR, A. B., M.D. Birm., M.R.C.P. Lond., First Assistant Medical Officer at the King Edward VII. Sanatorium, Midhurst.

THOMAS, E. W. P., M.B. Camb., Hon. Registrar to the Skin Department at St. Thomas's Hospital.

TROUP, JAMES, M.B. Manch., F.R.C.S. Edin., Hon. Surgeon in Ordinary to the Royal Hampshire County Hospital, Winchester.

Medical Referee under the Workmen's Compensation Act, 1925: For the Bury, Rochdale, Oldham, Salford (Circuit No. 5), and Manchester (Circuit No. 8) County Court Districts. Applications should reach the Private Secretary, Home Office, Whitehall, London, S.W.1, before August 3rd.

Committee.—Asst. School M.O.

£500.

Birmingham, Dudley-road Hospital.—Jun. M.O. At rate of £200.

Birmingham, Little Bromwich Hospital for Infectious Diseases.—Sen. Asst. M.O. £750.

Birmingham, West Heath Sanatorium.—Res. Asst. M.O. At rate of £250.

Birmingham and Midland Eye Hospital.—H.S. At rate of £130.

Bolton R £125.

Bradford At rate of £135.

Brighton, *Women's Hospital.*—Res. H.S. £130.

Buxton, Devonshire Hospital. H.P. Also Asst. H.P. At rate of £200 and £150 respectively.

Cambridgeshire County Council.—Asst. County M.O. £500.

ury, Kent and Canterbury Hospital.—2 H.S.'s. Each at te of £125.

, King Edward VII. Welsh National Memorial Associa- n.—Asst. Res. M.O. for South Wales Sanatorium. £200.

, East Lancashire Tuberculosis Colony, Barrowmore Hall.— .P. At rate of £150.

f London Hospital for Diseases of the Heart and Lungs, ictoria Park, E.—H.P. At rate of £100.

hire Hospital for Sick Children.—Res. H.S. At rate of 130.

ster Royal Infirmary.—H.S. to Eye and Ear, Nose, and hroat Depts. £175.

nought Hospital, Greenwich, S.E.—H.S. At rate of £110.

, King Edward Memorial Hospital.—Jun. Res. M.O. t rate of £150.

urne, Princess Alice Hospital.—Res. H.S. £150.

a Hospital for Sick Children, Southwark, S.E.—H.S. At ate of £120.

al Lying-in Hospital, York Road, Lambeth, S.E.—Jun. Res. M.O. and Anæsthetist. At rate of £100.

n-square Throat, Nose and Ear Hospital, Nr. Piccadilly- ircus.—Anæsthetist. £150.

sby and District Hospital.—Sen. and Junr. H.S. £200 nd £150 respectively.

ogate Royal Bath Hospital.—Res. M.O. £156.

, Middleton-in-Wharfedale Sanatorium.—Sen. Asst. M.O. 450.

ich, East Suffolk and Ipswich Hospital.—H.P. and H.S. Each £120.

y General Hospital and Poor Law Infirmary.—Asst. Res. M.O. At rate of £150.

ston-upon-Hull, Beverley-road Institution.—Two Asst. M.O.'s. Each £350.

aster Royal Infirmary.—Jun. H.S. At rate of £130.

Infirmary, Lancs.—Sen. Res. H.S. Also Jun. H.S. At rate of £175 and £150 respectively.

rpool, Bootle General Hospital.—H.P. Two H.S.'s. Also Cas. O. Each at rate of £150.

rpool, Broadgreen Sanatorium.—Res. Asst. M.O. £200.

lon Homœopathic Hospital, Great Ormond-street, W.C.— Gynæcological H.S. At rate of £100.

clesfield General Infirmary.—Second H.S. At rate of £150.

chester, Ancoats Hospital.—H.S. At rate of £100. Also Orthopædic H.S. At rate of £100.

chester, Christie Hospital and Holt Radium Institute, Withington.—Asst. Radium Reg. £400.

chester Ear Hospital, Grosvenor-square, All Saints.—H.S. At rate of £150.

chester Northern Hospital, Chatham Hill-road.—Hon. athologist. £100. Also Bio-Chemist for Pathological Dept. £120.

chester and Salford Hospital for Skin Diseases.—H.S. At rate of £150.

ropolitan Hospital, Kingsland-road, E.—Res. Cas. O. £100.

dlesbrough, North Riding Infirmary.—Third H.S. and Cas. O. At rate of £125 and £150 respectively.

ler General Hospital, Greenwich-road, S.E.—Anæsthetist. 52 guineas.

castle, Throat, Nose and Ear Hospital, Rye Hill.—H.S. £100.

thampton County Mental Hospital, Berrywood.—Deputy Med. Supt. £550.

wich, Jenny Lind Hospital for Children.—Res. M.O. £120.

tingham General Hospital.—H.S. for Ear, Nose, and Throat Dept. At rate of £150.

estry, Robert Jones and Agnes Hunt Orthopædic Hospital.— H.S. At rate of £200.

tsmouth City.—Tuber. O. and Sen. Asst. M.O.H. £750. Also Asst. M.O.H. and First Res. Med. Asst. £600–£750. Also Asst. M.O.H. and Second Res. Med. Asst. £500–£700.

incess Beatrice Hospital, Earl's Court, S.W.—Hon. Clin. Asst.

tney Hospital, Lower Common, S.W.—Res. M. and Cas. O. At rate of £100.

een's Hospital for Children, Hackney-road, E.—H.S. and Cas. O. Each at rate of £100. Also Sen. Res. M.O. At rate of £200.

ading, Royal Berkshire Hospital.—Cas. O. Also H.S. Each at rate of £125.

chdale Infirmary and Dispensary.—Jun. H.S. £200.

mford, Essex, Oldchurch Hospital.—Pathologist and Asst. M.O. £600.

yal National Orthopædic Hospital, 234, Great Portland-street, W.—Two H.S.'s. for Country Branch. Each at rate of £150.

yal Naval Medical Service.—Nine M.O.'s.

yal Northern Hospital, Holloway, N.—Two Clin. Assts.

Thomas's Hospital.—M.O. in charge of Physio-Therapeutic Dept.

effield, Children's Hospital.—H.S. At rate of £100.

effield Royal Hospital.—Two Res. Asst. Cas. O.'s. Also Res. Anæsthetist and Holiday Locum. Each at rate of £80.

effield, Royal Infirmary.—Ophth. H.S. At rate of £120. Also H.S. and H.P. Each at rate of £80.

ockport Infirmary. Hon. Ophth. Surgeon.

oke-on-Trent, Longton Hospital.—H.S. £160.

wansea General and Eye Hospital.—Cas. O. At rate of £150 to £175.

est Bromwich, Hallam Hospital.—Res. H.P. At rate of £200.

estminster Hospital, Broad Sanctuary, S.W.—Wander Scholar (Clin. Path. and Reg. to Children's Dept.). £250.

igan, Royal Albert Edward Infirmary and Dispensary.—H.S. At rate of £150.

illesden General Hospital, Harlesden-road, N.W.—Res. Cas. O. At rate of £100.

olverhampton Royal Hospital.—H.S. for Fracture and Orthopædic Dept. At rate of £100.

orcester R [illegible] so Jun. H.S. At rate of £160 ar [illegible]

orksop, F [illegible] At rate of £150.

Births, Marriages, and Deaths

BIRTHS

Broadbent.—On July 6th, at Queen's-gardens, W., the wife of Hubert Broadbent, M.R.C.S., of a daughter.

Evans.—On July 7th, at Edmonton, London, the wife of P. F. Evans, M.R.C.S., of a son.

Graves.—On July 8th, at Devonshire-street, W, the wife of Dr. T. C. Graves, of Birmingham, of a daughter.

Greaves.—On July 13th, at Dumfries, the wife of Surg.-Lt. W. Greaves, R.N., of twins (son and daughter).

Mackintosh.—On July 9th, the wife of Dr. Ian Mackintosh, Whitwell, Hitchin, of a son.

McBrien.—On July 4th, at Maidstone, Kent, the wife of L. P. McBrien, M.R.C.S., of twins (son and daughter).

Potts.—On July 6th, at Salisbury, the wife of J. L. Potts, B.Chir., of a daughter.

Williams.—On July 5th, at Sutton, Surrey, the wife of L. G. Williams, M.R.C.S., of a son.

Wraith.—On July 15th, 1935, to Jessie Evelyne Sheret, M.B., B.S., D.M.R.E., wife of F. Wraith, M.B., Ch.B., Foots Cray, Lymm, Cheshire—a son.

MARRIAGES

Bedford—North.—On July 13th, Davis Evan Bedford, F.R.C.P., to Audrey Selina North, eldest daughter of Mr. and Mrs. Milton Ely, of Sutton, Surrey.

Chappel—Hovey-Rhodes.—On July 6th, at Bowdon Downs Church, H. M. Chappel, B.Chir., to Margaret Sylvia Hovey-Rhodes.

Connell—Stannus.—On July 6th, at Windsor, Arthur Blackall Connell, M.D., to Edris Stannus (Ninette de Valois).

Craig—MacLeay.—On June 29th, at Singapore, Major Walter James Fairlie Craig, R.A.M.C., to Anita Esther Lloyd MacLeay.

Magnus—Aiken.—On July 13th, at St. Andrew's Church, Hampstead, Dr. H. A. Magnus, of St. Bartholomew's Hospital, London, to Kathleen Aiken, of Belfast, North Ireland.

Smith—Jennings.—On July 4th, at Rydal Church, Charles Edwin Smith, M.R.C.S., Ambleside, to Violet Jennings.

DEATHS

Bird.—On June 22nd, at Quetta, from earthquake injuries, Major Joseph Godfrey Bird, I.M.S., aged 45 years.

Campbell.—On July 4th, Henry Johnstone Campbell, F.R.C.P., J.P., of Dartmouth, formerly of Bradford, Yorks, aged 76.

Craig.—On July 3rd, at Kirkcudbright, Surg. Capt. John W. Craig, R.N. (ret.), aged 63.

Crawford.—On July 1st, at Edinburgh, John Crawford, M.D., Tayvallich, Argyll, late M.O.H. of County of Zetland.

Day.—On July 12th, at Colchester, William Leigh Maule Day, M.D., in his 59th year.

Field.—On July 3rd, at North Wallington, Surrey, George Hammond Field, M.B.

Grace.—On July 5th, Nathaniel Grace, M.D., of Tunbridge Wells, aged 65.

Heathcote.—On July 6th, Henry Charles Heathcote, M.B., Bath, aged 64.

Hughes.—On July 7th, after long illness, at Sydney, Samuel Henry Hughes, F.R.C.S., aged 71.

Manders.—On July 5th, at Chesham Bois, Lieut.-Colonel Horace Manders, F.R.C.S., in his 83rd year.

Myles.—On July 14th, at Folkestone, Edmond Henry Myles, Major R.A.M.C. (ret.), in his 79th year.

Peachey.—On July 7th, at Barnes, George C. Peachey, L.R.C.P.

Ralston.—On June 24th, in Johannesburg, Robert Gow Ralston, F.R.C.S., aged 62.

Reynolds.—On July 2nd, at High Wycombe, Lewis William Reynolds, M.R.C.S., J.P., aged 79.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

Monday, July 22nd, to Saturday, July 27th.—Blackfriars Skin Hospital, Blackfriars-road, S.E., afternoon course in dermatology. All Saints' Hospital, Austral-street, S.E., course in urology.—Courses and clinics arranged by the Fellowship are open only to members and associates.

HOSPITAL FOR EPILEPSY AND PARALYSIS, Maida Vale, W.

Thursday, July 25th.—3 P.M., Dr. Blake Pritchard: Clinical Demonstration.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

Thursday, July 25th.—2 P.M., Dr. D. Bateman: Methods of Testing for Asthma. 3 P.M., Dr. A. Signy: Pathological Demonstration.

Out-Patient Clinics daily at 10 A.M. and ward visits (except Wednesday) at 2 P.M.

INTERNATIONAL CONGRESS ON LIFE ASSURANCE MEDICINE.

Wednesday, July 24th to July 26th.—Congress at the offices of The Prudential Assurance Company (142, Holborn-bars, E.C.).

NOTES, COMMENTS, AND ABSTRACTS

DIMENSIONS OF SICK WARDS

THE dimensions of sick wards to be erected in the future at general hospitals under the management of the L.C.C. are being standardised. In submitting proposals to this end to the Council, the general purposes committee state that experience has proved that the comfort and well-being of the patient, and his efficient treatment, should be the determining factors in deciding the dimensions of a ward, and that if these be adequately provided for all other considerations and all theoretical formulæ can be disregarded The proposals made relate solely to the normal type of ward in which the beds are placed at right angles to the side walls. The experience of wards in which the beds are parallel to the side walls is not sufficient to warrant the laying down of standards.

The dimensions recommended are as follows:—

> That the standard width for all types of wards to be erected in the future at general hospitals be 26 feet and that the other dimensions of the wards be as follows: (i) *acute wards*, including maternity, tuberculosis, venereal diseases, and acute mental wards—wall space per bed, 8 feet; height, 11 feet up to a length of 50 feet and 12 feet when the length exceeds 50 feet; (ii) *chronic wards*—wall space per bed, normally 7 feet, but when offensive cases are treated in the ward, 8 feet; height, as for acute wards; (iii) *cot wards*—wall space per bed, 7 feet; height, as for acute wards; (iv) *single-bedded wards*—to be not less than 11 feet by 10 feet and the height to be 10 feet or in conformity with the general plan.

Subject to certain reservations, these standards will be applied to existing wards as soon as the position with regard to accommodation makes it practicable. The proposals for the acute wards give a floor space of 104 square feet for each patient, and a cubic capacity of 1144 cubic feet per patient. This cubic capacity is less than was formerly considered desirable because in the past great importance was attached to height of wards as providing additional air space, and lofty wards up to 16 feet in height were the rule, generally with quite inadequate window space. It is now known that any increase in the height above 12 feet does little or nothing to improve the condition of the air, and that satisfactory ventilation depends on adequate window space and its proper use. It is, therefore, considered possible to reduce the height of wards as compared with the old standards without detriment to their condition or appearance, and with considerable saving in building costs. No ruling for length of ward is laid down, but the committee state that it is improbable that unbroken wards as long as 100 feet will ever again be constructed.

BIG-GAME PHOTOGRAPHY

IT is refreshing sometimes to be transported from a common-place world to one where not only success in enterprise but actual survival depends on exceptional physical fitness and a reaction time quicker than the normal. Mr. Cherry Kearton[1] has had exciting adventures with animals and men to which his fascinating photographs bear witness, and has many tales to tell. One of his objects in describing and picturing his adventures is to encourage the big-game hunter of the future to substitute the camera for the rifle, and to this end a less constant insistence on the perils of the jungle and coast would have been more effective. Those who read of the frequent occasions on which Mr. Kearton narrowly escaped falling from the top of a cliff on to sea-washed rocks or avoided savage attack from his camera subjects may find it difficult to understand why he should rate the preservation of his life so much lower than the preservation of his negatives. They may even decide, realising the extent to which the photographer must needs rely upon his good fortune, that they will not risk emulating his experiences without providing themselves with a serviceable rifle. But with all endeavour to preserve animal types we have deep sympathy; the safety of society demands their removal in many places, but biological research would certainly suffer from their extermination.

SOME METHODS OF HEALTH EDUCATION[1]

A LITTLE book intended for school-teachers should prove useful to all those who are concerned with health propaganda. Its object is not to teach hygiene but to suggest how to inculcate good habits, instil knowledge, and promote a right attitude to personal and communal problems of health. The titles of the four chapters indicate the line of approach: The Aims and Values of Health Education, the Content of the Health Education Course, School Methods and the Gaining of Health Knowledge, and Teaching Aids in Health Education. There are 27 illustrations giving point to the text. If it can be assumed that teachers have themselves the right kind of knowledge, it would be difficult to find a better presentation of the way in which it should be applied. Where the authors refer to points in hygiene they are nearly always accurate. The book can be commended to education authorities and bodies responsible for the training of such officers as health visitors.

WOMEN OVER FORTY

A SIMPLE, friendly book has been written by an American author[2] for women who have reached the traditionally dispiriting age of 40, after which, they are urged to believe, they may embark on the "golden years" of their lives. The book contains nothing that is new or informative for the medical reader; but it may well prove serviceable for recommendation to women patients who evince the psychological and physical difficulties of the menopause in a pronounced form.

THE "ALBATROSS"[3]

THIS pious biography by a grandson introduces us to the interesting personality of a Newfoundland doctor, still living, who has carried on a large practice for many years mainly by visits across the sea in his own yacht, the "Albatross." It is an interesting little story of personal courage, energy and resource, and we agree with Mr. Fitz-Gerald that when the hero of the book dies he will leave behind him a long record of service to his fellow-men.

SUN-BATHING

APPROPRIATE to the season is a little brochure[4] by Mr. I. O. Evans on sun-bathing, both "ordinary" and what the author is pleased to call "complete." It deals with practical and psychological problems of nudism, and gives a bibliography, a list of sun-bathing organisations, and of the seaside resorts which permit men to bathe in slips or trunks.

ADDRESSES AND ORIGINAL ARTICLES

INFECTION AND ITS CONTROL IN CHILDREN'S WARDS *

BY E. H. R. HARRIES, M.D. Lond.

MEDICAL SUPERINTENDENT, NORTH-EASTERN HOSPITAL
(LONDON COUNTY COUNCIL)

LECTURE I

THE problems of ward infection in their various aspects have within the last few months been debated both in the medical press,[1] and at meetings of medical societies.[2] Cross-infection is the bane of the staffs of both children's and fever hospitals, which are, to all intents and purposes, children's hospitals with a limited clinical field. At one time this clinical field was much more limited that is the case now that the large fever hospitals admit every variety of zymotic disease whether notifiable under the Infectious Diseases Notification Acts or not. The practical effect of this extension of the clinical field, from the medical and administrative points of view, has been the admission of large numbers of children of the younger age-groups suffering from such diseases as epidemic diarrhœa, whooping-cough, and measles.

Upon the consequences of extraneous infection it is unnecessary to dwell. They may be perilous to the individual child ; they are always, in some degree, detrimental to the hospital. Long detention, especially if the cause be some superimposed infective process, may result in that complex of physical and psychical deterioration known as hospitalism. From the administrative standpoint, if wards are encumbered by long-stay patients or closed to new ones, the machinery of admission and discharge breaks down. The overhead charges remaining undiminished, the average cost of the patients treated rises. Equally important, the reputation of the individual institution or of institutions of its particular type inevitably if insensibly suffers.

Sources of Infection

The sources of infection of any type in children's wards may be classified as those : (1) *External to the hospital :* the household, creches, infant welfare centres, schools, and cinemas. (2) *External to the wards :* waiting rooms, casualty rooms, out-patient departments, or the receiving rooms of fever hospitals. Although obviously infective children are promptly segregated pending final disposal by the medical staff, some must escape notice until the damage is done. (3) *Within the wards :* children inadvertently admitted in the incubation period or prodromal stage of an acute-infective condition ; unrecognised *formes frustes ;* carriers amongst either patients, staff, or visitors.

The extraneous infections which from time to time are so introduced fall into the following categories :—

A. Acute infections of the upper respiratory tract.—(1) Common specific infections, seven in number. Three of these (diphtheria, scarlet fever, and whooping-cough) are bacterial diseases ; four (measles, rubella, mumps, and chicken-pox) are caused by viruses. (2) Non-specific, or rather unspecified infections of bacterial, viral, or combined origin. These unspecified infections may be superimposed upon those of the specific group, and are the chief causes of the major complications of two of them, namely, measles and whooping-cough.

B. Acute infections of the gastro-intestinal tract.—Discarding protozoal and helminthic infections, the intestinal infections fall into two groups : (1) Primary, those caused by the ingestion of organisms of the *B. coli*-paratyphoid-dysentery group, which are thus to a large extent specific infections ; and (2) secondary. These are brought about by the ingestion of organisms derived from primary upper respiratory tract infections. Occasionally the intestinal infection may be primary and the respiratory tract infection secondary.

C. Cutaneous infections.—(1) Pyococcal, such as impetigo contagiosa and paronychia. (2) Parasitic, such as pediculosis, scabies, and the tineas.

D. Genito-urinary infections.—(1) Pyelitis and cystitis. (2) Vulvo-vaginitis : (*a*) venereal, and (*b*) non-venereal.

To a considerable extent the incidence of extraneous ward infections depends upon the type of work carried out in the institution, since this determines the age-groups of the children likely to be admitted and the length of time they remain. Age-grouping has clearly an important bearing upon the type of infection likely to be introduced and the chances of its dissemination among any particular ward population. The average length of stay governs the number of children admitted to the wards and thus the opportunities for the introduction and transference of infection.

If the average stay is short, implying a large number of admissions, it is impossible, as a general measure, to impose, for an adequate length of time, a preliminary period of quarantine or to undertake active immunisation, methods of general and specific prophylaxis which are feasible when the stay is likely to be long and the admissions, as a result, relatively few in number.

On a basis of length of stay hospitals for the treatment of children fall into three groups : (1) *General children's hospitals,* exemplified by the voluntary children's hospitals, which admit patients from the neonatal period up to the age of 12–14 years and retain them for three days or less up to two or three weeks at the longest. Many of these institutions have convalescent branches in the country. (2) *Special hospitals* for children suffering from orthopædic, tuberculous, or rheumatic conditions, and whose stay may extend over many months. (3) *Fever hospitals,* most of whose patients are children brought by ambulance either direct from their homes or from other institutions. The average length of stay exceeds a month.

Children's hospitals all possess isolation accommodation for use in emergency or for special cases, but, in this country, they are ordinarily concerned with the common fevers only as sources of infection to other patients. So far as possible, children suffering from the exanthemata are removed to fever hospitals. From the point of view of students this removal is in many ways unfortunate, since there is a tendency, when certain diseases are treated in special institutions, to regard the diseases themselves as something essentially different, instead of integral parts of general medicine.

Although fever hospitals are no longer seriously regarded as having any appreciable effect upon the incidence of the endemic fevers in the community, yet since every patient at the time of admission is deemed to be a potential source of infection, it is necessary to secure that, so far as possible, infectivity has ceased before discharge from hospital. Thus length of stay in the fever hospital is always determined by two factors : physical fitness and freedom from infection. Depending upon the disease, either of these two states may precede the other by a considerable interval. Unfortunately there is a third factor, extraneous infection of any kind which, however trivial clinically, may, by prolonging infectivity, add very greatly to the average length of stay of patients.

---

* The Milroy lectures for 1935, delivered before the Royal College of Physicians of London.

The fever hospital must retain its patients until any potential source of infection whatever has been eliminated.

Within recent years the average length of stay of patients in many fever hospitals has been reduced very considerably, not only without detriment to, but to the great advantage of the patient and without any increase, but a decrease rather, in the return-case rate. Under the conditions obtaining in open wards, it may be said that the longer a child remains in the milieu of infection, the longer is he likely to remain, and the more difficult is it to secure bacteriological righteousness; in a word, he becomes hospitalised.

The chief reduction in the average days' stay has taken place in the case of scarlet fever. The traditional period of detention of six weeks has become for the uncomplicated case a month. This reduction has been brought about primarily by the disregard of desquamation, justified by the work of the Dicks, but also by the mild type of the disease, with a lessened incidence of complications. This incidence has been reduced still further, in the belief of many, by the use of scarlet fever antitoxin. Another factor which has operated to reduce the length of stay of scarlet fever patients has been the segregation and specialised treatment by otologists of patients suffering from middle-ear disease, at one time a most enduring and reputedly most infective complication.

Incidence of Infection in Children's Wards

SPECIFIC

Some recent figures of the incidence of the specific infectious diseases in the wards of the three different types of institution mentioned above may be given (1) During 1933 it is recorded [3] that among 3561 patients admitted to a large provincial children's hospital, there occurred 136 cases of infectious disease or 3·8 per cent. of the admissions. Of these, 79 (58 per cent.) developed in hospital within their respective incubation periods and 41 (30 per cent.) were contracted in the wards. The origin of 16 cases was unknown The two infections most frequently introduced in the incubation period were scarlet fever and measles. Being exceptionally well provided with isolation accommodation this hospital was able to retain over 40 per cent. of the patients who were unsuitable, for one reason or another, for removal. The opinion is expressed by the reporter that the figures would possibly have been worse but for the passive immunisation of contacts and for the existence of the isolation block.[2]

(2) Agassiz [4] reports that during ten years at the High Wood Hospital for tuberculous and rheumatic children of all ages up to fifteen years, amongst 7000 admissions, an average of 700 annually, the incidence of infectious diseases, diphtheria and scarlet fever mainly, ranged between 3 and 4 per cent. Of these cases, 25 per cent. occurred within the incubation period; 60 per cent. arose independently of any ascertained cause and "appeared to have been due to visitors." The small number of contact cases (15 per cent. of the total) Agassiz ascribes to the open-air methods of treatment.

(3) An analysis of the admissions to the North-Eastern Fever Hospital (661 beds) for twelve months (October 1933, to September, 1934) is summarised in Table I.

Although scarlet fever and measles were epidemic in London throughout the greater part of the period, chicken-pox was the disease chiefly responsible for the numerous cross-infections shown in Table I.

TABLE I.—*Admission to North-Eastern Fever Hospital in Twelve Months*

—	No.	Admissions per cent.
1. Total admissions	5712	—
2. Diagnosis doubtful (isolated)	639	11·1
3. Double infection on admission (isolated)	180	3·1
4. Incubating second disease and inadvertently admitted to open wards.	172	3·0
5. No. of cross-infections arising from 4 ..	221	3·8

As extraneous infections, the common fevers provide problems for the medical administrator rather than for the clinician. Chicken-pox, rubella, and mumps are negligible as causes of mortality, and although diphtheria, scarlet fever, whooping-cough, and measles are regarded as the four major specific infections of children, their relative importance as causes of mortality has declined very greatly during the past seventy years. Even if one of these four infections does make its appearance in a ward, passive immunisation of contacts is possible in the case of three of them—*viz.*, diphtheria, scarlet fever and measles.

An analysis of 118 consecutive introductions of specific cross-infections into open wards of the North-Eastern Hospital is set out in Table II.

TABLE II.—*Cross-infections*

Disease.	No. of introductions.	No. of ward outbreaks	Remarks.
Diphtheria.	32	0	Schick test, swabbing and virulence tests, passive immunisation of contacts.
Scarlet fever.	36	0	Dick test, swabbing for carriers of hæmolytic streptococci, passive immunisation of contacts.
Measles.	7	3	Adult immune serum used for prevention or attenuation.
Rubella.	7	1	Outbreak among adolescents, not young children.
Whooping-cough.	23	0	—
Chicken-pox.	13	9	Two outbreaks followed admission of children who developed herpes zoster.

It should be added that in this hospital the space between bed-centres is not less than twelve feet, and, in some wards, fifteen feet. The factor of wall space in the dissemination of upper respiratory tract infections will be referred to again.

NON-SPECIFIC INFECTIONS

The incidence in children's wards of extraneous acute infections other than the specific fevers must ordinarily be stated in general terms, so varied is their ætiology and so diverse are their clinical manifestations. Hutinel [5] long ago recognised that the chief enemy of children in hospital was the streptococcus, and emphasised the gravity of the results of dissemination of respiratory, gastro-intestinal, and cutaneous infections. All are agreed as to the outstanding importance of infections of the upper respiratory tract, although, as Spence [6] remarks, a respiratory or tonsillar infection which may be harmless in a five-year-old child may become very serious when transmitted to an adjacent infant.

Whatever their clinical results, the incidence of gastro-intestinal and cutaneous infections is lower by far and their control much easier than those of the respiratory tract.

Primary *gastro-intestinal* infections chiefly occur, as Paterson and Nabarro[7] have shown, amongst infants from three to nine months and, as Nabarro and Signy[8] have pointed out, attacks of gastroenteritis and ileo-colitis are frequently dysenteric. They find that the Sonne strain is often responsible and this has been my own experience in recent years.

The introduction of diarrhœa or dysentery into a children's ward may be unavoidable, but save in those very exceptional cases where the source has been a infected milk-supply, dissemination is due to defective nursing technique.

From the point of view of dissemination the most troublesome *cutaneous* infections are pyococcal—e.g., impetigo contagiosa and infantile "eczema" so-called. Hutinel and Rivet[9] state that, failing rigorous aseptic precautions, a patch of infantile eczema may be the source of rapidly fatal broncho-pneumonia or septicæmia not only in the original patient but amongst other children in the ward. Schwartz[10] records that of 10 infants admitted to hospital for the treatment of infantile eczema four died of fulminating broncho-pneumonia and two of intestinal intoxication. Impetigo may be a cause of prolonged detention in a fever hospital. Unless the primary case is promptly isolated, carelessness in, for example, the matter of towels may result in transference to other children.

Owing largely to the work of the school medical service and its associated dermatologists, tinea tonsurans and scabies are now of comparatively rare occurence in the wards of fever hospitals where so many children are of school age. Early detection of microsporon ringworm is now easy by means of the mercury vapour lamp with Wood's glass which is available in all the infectious diseases hospitals of the London County Council.

Neither of the foregoing groups is to be compared in importance with extraneous infections of the upper respiratory tract. Brennemann[11] is of opinion that the major cause of hospitalism in infants to-day lies in infections of the upper respiratory tract and their complications and he thinks that a significant ætiological shift may have occurred from the gastro-intestinal to the respiratory tract with diarrhœa and indigestion as prominent symptoms common to both.

Parsons[12] considers that while the chief causes of death in the first half of the neonatal period are antenatal, in the second half they are mainly the result of postnatal infection particularly of the respiratory system, the source of which is to be found amongst those who have charge of the child, thus agreeing in the main with the conclusions of Cruickshank[13] as to the major causes of neonatal mortality. Bruce Young[14] notes the remarkable liability of the London slum infant under the age of three months to infection of various mucous membranes due to bad hygienic conditions. Diarrhœa and vomiting may be the most serious manifestation of the catarrhal syndrome and he thinks that sputum, possibly infected with the hæmolytic streptococcus, gives rise to an infective gastritis particularly in association with outbreaks of influenza in the winter months.

During the biennial epidemics many fever hospitals now admit large numbers of children suffering from measles who thus provide opportunities for study of the incidence and transference of concomitant upper respiratory tract infections. It must be emphasised, however, that infants under three months of age very rarely indeed contract measles and thus representatives of the youngest age-groups who occasion so much anxiety in general children's hospitals are but few in the measles wards of fever hospitals. Among infants between three and six months of age measles is frequently modified. All the gradations observable in measles artificially attenuated by human immune serum may be noted in attacks of the natural disease amongst this group who presumably still possess remnants of maternally transmitted passive immunity. After the age of six months, measles is usually unmodified. The high mortality of young children is caused, of course, not directly by the specific viral infection but by concomitant or superadded bacterial infections. The rôle of the virus in the common cold or measles is, according to Shibley, Mills, and Dochez[15] to cause initial inflammation and so facilitate the activities of the common coccal organisms always present in the nasopharynx. The virus of measles rapidly dies; its presence in the blood in the early stages of the disease stimulates the production of specific antibodies which in a few days render the child solidly immune to a second attack. Unless the primary attack has been very greatly modified in the partially immune infant or too much attenuated by serum, second attacks of measles are, to say the least, extremely rare.

The medical administrative problem provided by the hospitalisation of measles is thus to reduce the dissemination of concomitant upper respiratory tract infections to a minimum.

On the continent the dire results of hospitalisation recorded by such observers as Wladimiroff[16] and Debré and Joannon[17] were recognised as being due mainly to overcrowded wards and the remedy was found in segregation and asepsis. Duncan Forbes[18] considers that so alarming is the mortality of measles patients in hospital, chiefly because of the rapid dissemination throughout the ward of organisms giving rise to fatal broncho-pneumonia, that unless they can be nursed in cubicles or under open-air conditions they will do better at home. The allowance of space in the wards upon which he founds his conclusions is not stated. Peters,[19] however, compared two groups of measles patients admitted from poor homes, a good many suffering from complications. Of 167 children who were nursed in a large ward of 26 beds with an allowance of 1400 cubic feet of air space and 96 square feet of floor space and were thus in his view "not overcrowded," 23 died, a case-mortality rate of approximately 14 per cent. A further 150 unselected patients were treated in an isolation ward containing four cubicles with four beds in each. Of these patients only 6 died, a case-mortality rate of 4 per cent.

That the treatment of measles patients in open wards is not necessarily associated with a high case-mortality is shown by the experience of the infectious diseases hospitals of the London County Council. In London, measles patients have been admitted to the fever hospitals formerly under the control of the Metropolitan Asylums Board, but now under that of its successor the London County Council, since 1910. Within recent years the successive epidemics of measles in London have been described by Sir Frederick Menzies in a series of special reports,[20] and Brincker[21] has discussed fully measles mortality with particular reference to London and to hospitalisation. The numbers of measles patients admitted and the case-mortality in recent epidemics are indicated by the following figures:—

Epidemic.	Cases admitted.	Case-mortality per cent.
1927–28	8,729	7·0
1929–30	6,512	6·5
1931–32	11,526	5·6

The complete figures of the 1933–34 epidemic are not yet available, but to the North-Eastern Hospital alone during nine months (October, 1933, to June, 1934) 1603 measles patients up to the age of fifteen years were admitted. The case-mortality was 5 per cent. Table III. shows the cases divided into age-groups.

TABLE III.—*Measles Patients Admitted to the North-Eastern Hospital up to the Age of 15 Years during the Nine Months, October, 1933, and June, 1934*

Age-group.	Cases.	Deaths.	Case-mortality.
0–½	24	2	8·3 per cent.
½–1	200	25	12·5 ,,
–2	590	45	7·6 ,,
–3	333	6	1·8 ,,
–4	210	6	2·8 ,,
–5	107	2	1·8 ,,
5–10	127	—	—
10–15	12	—	—
	1603	86	5·0 ,,

The graphs which have been constructed from the quarterly figures summarised in Table III. show that neither in numbers nor in age-incidence were the admissions during the period October to December, 1933, comparable with those of the two succeeding quarters (Fig. 1). The epidemic had not gathered way and the children admitted did not fairly represent the normal age-incidence of the disease when epidemic. The graphs constructed for the two succeeding quarters, although of different dimensions, are almost identical in form and reflect, with considerable accuracy, the age-incidence of measles during that epidemic. The number of fatal cases in each age-group is shown in black; none occurred amongst children over five years old. The lessened incidence of broncho-pneumonia upon admission during the April–June quarter due purely to seasonal causes accounts for the low case-mortality rate which was only 4·3 per cent. as compared with 6·8 per cent. in the October-December quarter and 5·7 per cent. during January to March. As already stated, the case-mortality based upon the figures for the whole period of nine months was 5 per cent.

It may be, as Cameron [22] remarks of the 1931–32 epidemic, that the large number of patients admitted probably indicated less discrimination in the removal of patients to hospital. In any case, it is obvious that the great majority must, of necessity, have been nursed in ordinary wards; to provide cubicle accommodation upon such a scale is not feasible.

The wards in which these patients were nursed were of the simplest "temporary" pavilion type, abundantly cross-ventilated by windows looking out upon grass airing courts. The normal complement of a ward was twenty patients. At the height of the epidemic no more than two additional cots were permitted and these were placed in the centre of the ward in such a way that whether lateral or central in position 12 feet was always maintained between cot centres or cot heads. Children with broncho-pneumonia were nursed in the open wards throughout; those with otitis media or enteritis were nursed "in barrier" within the ward in the first instance, but, as soon as possible, were removed to special wards in the case of otitis media or to cubicles in the case of enteritis.

Experience showed that the aggregation of children with ear discharge in a special ward brought dangers of its own. It was observed that after each fresh admission there was a tendency for other discharging ears to light up; obviously they had become reinfected almost certainly by manual transference. In one such ward accumulation of these foci of hæmolytic streptococcal infection culminated in an outbreak of scarlet fever, there being no other discoverable source of infection. At the same time, it must be pointed out that the removal of children with discharging ears to special wards did reduce potential sources of infection in the ordinary measles ward.

The predominant concomitant organisms recovered in routine swabbings of the nose, throat, or discharges from the ear either upon admission or at later stages were hæmolytic streptococci. Even in the April-June quarter during which the incidence of respiratory complications upon admission showed the usual seasonal decline, 40 per cent. of all children admitted to one ward over a period of three months harboured, at the time of admission, hæmolytic streptococci in the upper respiratory tract, the organisms frequently being present in pure culture. Helmholz [23] in a special group of children suffering from upper respiratory tract infections recovered hæmolytic streptococci in 49 cases out of 98 (50 per cent.). He thinks that the mere presence of these organisms is of no significance. If, however, they form at least 10 per cent. of the flora they may be of ætiological importance.

Griffith [24] concludes that the invasion of a human

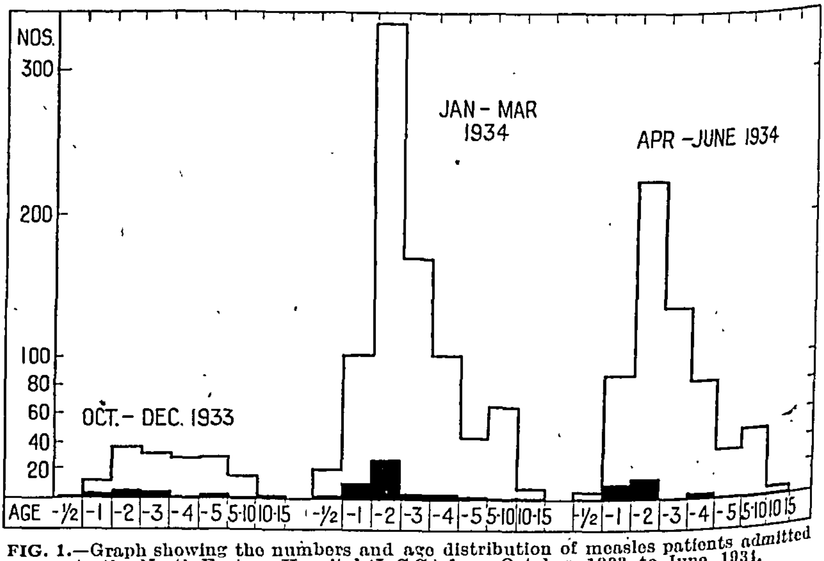

FIG. 1.—Graph showing the numbers and age distribution of measles patients admitted to the North-Eastern Hospital (L.C.C.) from October, 1933, to June, 1934. (Black columns indicate deaths.)

community by a hæmolytic streptococcus of known serological type and its spread amongst individuals forming the community may produce a whole series of clinically different diseases. In any measles ward foci from which upper respiratory tract infections may be disseminated by one means or another are obviously abundant. As the result of consecutive field swabbings of the same children at an interval of days, evidence was obtained that dissemination of hæmolytic streptococci had in fact occurred after admission, although the infection was not necessarily or ordinarily of sufficient magnitude to produce clinical effects. The uncomplicated case of measles must be regarded as, potentially, a minor focus of infection. The major foci are those children who are suffering from the complications of the disease. Their infectivity is greater, and since these are the patients who require most attention from the staff, the opportunities for spread by mediate means are more numerous.

The higher the proportion of children actually suffering from or developing complications at the time of admission the greater the risk of transference of infection to children admitted with uncomplicated attacks of measles. Although, without a doubt, some children develop complications late in the attack as the result of the extension of an upper respiratory tract infection which was present at the time of admission, many of the complications of late onset must be debited to hospitalisation; the upper respiratory tract has been infected or reinfected in the ward.

Incidence of Complications

The three main complications of measles are broncho-pneumonia, otitis media, and enteritis. As to whether, on admission, broncho-pneumonia was developing it was not always easy to be sure and we were frequently able to avail ourselves of the opinion of Dr. Helen Mackay who was at the time making independent investigations upon vitamins. Systematic examination upon admission of the drum-heads of all children in her wards enabled Dr. Hilda Linford to obtain early evidence of middle-ear infection which did not necessarily result in perforation and discharge, but, in what follows, otitis media is synonymous with otorrhœa. I have assumed that complications occurring during the first week of disease, which meant in practice that they were present upon admission or became evident within two or three days thereafter, might fairly be agreed to be beyond the control of the hospital, but that those appearing during the second week or later of the disease must be regarded as of true post-admission origin. An analysis of the incidence during nine months of the three main complications amongst 1464 patients up the age of five years has been made; over that age, complications were both clinically and statistically negligible. The numbers of children in each age-group are the same as those already given in Table III.

Summarised, the analysis shows that the incidence of *broncho-pneumonia* upon admission or within the ensuing two or three days was, at the ages up to five years, 12·3 per cent. with a case-fatality rate of 30 per cent. It is notable that no infant in the small group of 24 under six months old had broncho-pneumonia on admission or developed it subsequently.

Infants of from six to twelve months showed an ncidence of 17·5 per cent. and the high fatality-rate of 51·4 per cent. Amongst children aged from one to two years the incidence (17·3 per cent.) was practically the same but the fatality-rate, 36·2 per cent., improved. Compared with those of children up to one year of age the incidence and fatality-rates of broncho-pneumonia amongst those of from two to five years old were both approximately halved.

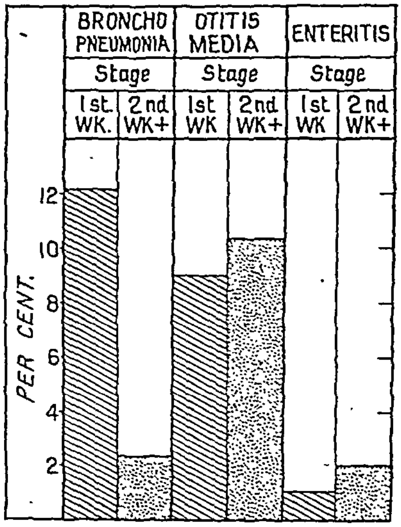

FIG. 2.—Percentage incidence of measles complications in first and subsequent weeks of the disease (North-Eastern Hospital).

Broncho-pneumonia of *late* onset (second week and onwards) occurred in 39 cases, or 2·6 per cent. of the admissions up to five years of age. The fatality-rate was 28 per cent. With the exception of one fatal case in a child of five years, the deaths occurred entirely amongst those aged from six months to two years.

Otitis media (otorrhoea) was present upon admission or occurred very shortly afterwards in 7 per cent. of all cases up to five years of age. Here the maximum incidence (20·8 per cent.) fell upon infants under six months old. It was 7 per cent. among those aged from six to twelve months; 9·3 per cent. from one to two years; 5·4 per cent. from two to three years and fell progressively from that age onwards to 2·8 per cent. among children from four to five years old. Otitis media of *late* (post admission) onset occurred in 8·6 per cent. of the whole series. In the various age-groups the incidence was as follows; under six months, 12·5 per cent.; six to twelve months, 11 per cent.; one to two years, 8·3 per cent.; two to three years, 6 per cent.; three to four years, 9·5 per cent.; four to five years, 10·3 per cent. The fluctuations were thus very much less in the different age-groups than was the case in otitis media of early onset and this is possibly suggestive.

There were no fatalities directly ascribable to ear complications in either the early or late group; nevertheless the clinical importance of this complication is obvious. Administratively, otitis media is the most important complication of measles. The frequency of its late occurrence is to the medical administrator a sensitive index of the character of the nursing in the ward. Some wards containing children of similiar age-distribution consistently produced many and others very few cases of late otitis media. The normal days' stay in hospital of children with uncomplicated measles was 14 days, but since it was our aim to release no child with a discharging ear or, if possible, with an unhealed drum head, it is clear that the average days' stay of all cases was increased considerably by the occurrence of this complication.

Enteritis, presumably secondary to an upper respiratory tract infection, occurred as an early complication in 1·5 per cent. of all children up to five years of age. The fatality-rate was 33·3 per cent. Except in infants under six months of age broncho-pneumonia was a usual concomitant in the fatal cases. The incidence was practically confined to children up to the age of two years. Only 2 cases occurred above that age.

Enteritis of *late* onset occurred in 30 cases (2 per cent.). Four of these cases were actually Sonne dysentery; an explosive outbreak in the five-year group, the origin of which was not traced. Apart from these four cases, the incidence of enteritis late in the attack of measles was entirely confined to children of from six months to three years. There were no fatalities amongst the 30 cases. The percentage incidence, early and late, of these three complications is shown in Fig. 2.

It seems reasonable to conclude from the foregoing results that adequate ventilation and a space between bed or cot-centres of 12 feet are not in themselves sufficient to prevent the dissemination of upper respiratory tract infections amongst measles patients if patients suffering from broncho-pneumonia are nursed in the ward. If it be held that under such conditions broncho-pneumonia, as a late complication, results from the aerial transmission of infection, then it is clear that any lesser spacing must be inadequate. *But ventilation and bed-spacing are not the only* factors in limiting the dissemination of upper respiratory tract infections in measles wards; they do not directly influence the spread of infection from children suffering from otitis media. From such a focus spread is not aerial but manual.

The types of upper respiratory tract infections, their dissemination in wards and the means of control available it is proposed to discuss in the next lecture.

SOUTHAMPTON MUNICIPAL HOSPITAL.—An extension to the nurses' home, providing room for another 40 nurses, has been opened at this hospital.

KENT AND CANTERBURY HOSPITAL.—The Duke of Kent has laid the foundation stone of the new building of this hospital, which has been associated with East Kent since 1793. The existing accommodation, provided by a building erected nearly 150 years ago, is now inadequate. For seven years efforts have been made to raise the £120,000 required for a new hospital and £30,000 remains to be collected. The building will be in the form of a triangle, the sides of which will face south, east and west and it will be constructed largely of concrete.

DEPRESSION OF MUSCLE TONUS

AS THE CAUSE OF ATELECTASIS, FAILURE OF THE CIRCULATION, AND OTHER POST-OPERATIVE SEQUELÆ

BY YANDELL HENDERSON, Ph.D.

PROFESSOR OF APPLIED PHYSIOLOGY, YALE UNIVERSITY,
NEW HAVEN, CONNECTICUT, U.S.A.

TONUS is one of the essential conditions of life. More fundamentally than any other feature, tonus differentiates a living man from a corpse. Many of the reflexes depend upon the existence of tonus and are abolished with its loss. Posture, particularly the ability to stand erect, is largely dependent upon tonus. It is loss of tonus that renders an acutely ill patient incapable of getting out of bed, or even of sitting up without assistance. The strongest man, after undergoing an abdominal operation, is for a time unable even to lift his head from the pillow. His condition expresses an acute depression of tonus.

These facts are such commonplaces of daily clinical observation that their fundamental significance is generally unrealised. Accompanying or following any considerable depression of tonus, and in general correspondence with the degree of depression, other post-operative sequelæ also occur. The lungs are partially deflated, and some degree of atelectasis commonly develops. The circulation is more or less depressed. Metabolism, heat production, oxygen consumption, and carbon dioxide production are all diminished. And it is now becoming evident that for all of these conditions there is one general cause: depression of the tonus of the musculature of the body.

MUSCLE TONUS AND RESPIRATION

As Hess[1] has pointed out, the movements of breathing have less the character of voluntary contractions of the respiratory muscles than they have of alterations between higher and lower degrees of tonus in these muscles. This is particularly the case in the diaphragm. It is probable that from the first breath of life until after the last the diaphragm is never for an instant completely relaxed.

How completely the maintenance of the inflation of the lungs and the prevention of atelectasis are dependent upon the tonus of the thoracic muscles and diaphragm may be illustrated by the following observations, which were made some years ago during a study of various methods of manual artificial respiration.[2]

A cat was placed under moderate chloroform anæsthesia; its trachea was connected with a small spirometer; and the volume of air breathed in a minute was recorded. A fatal dose of chloroform was then quickly admistered; and respiration and the heart action stopped finally. When the trachea was again connected with the spirometer, and artificial respiration was again performed by squeezing the thorax and abdomen, a nearly normal volume of air was at first expelled from the lungs; and when the pressure upon the thorax was released, the same volume of air was drawn in again. This inspiration was entirely due to the elastic recoil of the thoracic muscles and diaphragm. But, as the centres in the nervous system failed under asphyxia, the elasticity of these muscles was gradually abolished; and the thorax was re-expanded less and less. A progressively diminishing volume of air was drawn in each time that compression was released, until after about ten minutes, when the body was entirely flaccid, there was no movement of air whatever in or out of the lungs. Compression of the thorax and abdomen by the operator's hands then caused no air to be expired, for the chest was already deflated. And no air was drawn in; for the elastic recoil of the muscles was abolished with the entire loss of tonus.

This loss of tonus, abolition of elasticity and collapse of the chest are not mere laboratory observations on animals. A similar observation has been made by Dr. H. W. Haggard[3] on a man just dead from a heart attack. At first manual artificial respiration expelled air from the lungs, and the tonic elasticity of the chest drew air in again. Then as tonus decreased, the elastic recoil diminished until the thorax was deflated down to the size natural in a corpse.

A similar, if less extreme, observation was made twenty years ago upon normal men as part of a regular class exercise for medical students.[4] The manual prone pressure method of artificial respiration was applied by one student to another; and the volume of pulmonary ventilation thus induced was determined. This volume was found to be in all cases almost exactly the same as that of natural breathing. This observation was at first very surprising until its explanation was found. It means that in a normal man the respiratory centre regulates the tonus of the thoracic muscles and diaphragm with such precision that the chest expands to exactly the degree needed, alike after each normal expiration and each artificial compression. The pulmonary ventilation is thus adjusted not only to supply oxygen, but also to remove exactly the amount of carbon dioxide that the body produces: no more and no less. The subjects then performed voluntary forced breathing for a couple of minutes, so as to over-ventilate the lungs. Thereafter quite involuntarily they breathed subnormally for a time, or even stopped entirely. And when artificial respiration was applied during this period of apnœa, it was found that very little air was moved out of the chest and correspondingly little was drawn in.

These observations have recently been verified by X ray pictures[5] which show that in apnœa, after forced breathing, the position of the diaphragm is that of normal expiration, or even more deflation. Evidently the elasticity that normally keeps the thorax expanded is not a mere mechanical condition; it is rather a vital property under the control of the nervous system and particularly of the respiratory centre. Under normal conditions the chief stimulus to that centre is carbon dioxide. If that stimulus is diminished artificially by over-breathing, the tonus of the respiratory muscles is correspondingly diminished. In the far greater depression of tonus that follows long anæsthesia and extensive surgical operations, the chest cavity is so much decreased that the lungs are nearly deflated. A healthy man, even in expiration, has more than twice as much air in his lungs as a corpse.

In accord with these statements, observations upon patients by a number of observers[6] have shown that after surgical operations the vital capacity—that is, the maximum volume of air that a patient can inhale and exhale—may be decreased by as much as 50 per cent. In this decrease it is evident that the relaxation of the diaphragm plays a major part; for in X ray pictures its shadow may be nearly 5 cm. headward from its normal position.[7] This is as far as, or even farther than, the diaphragm moves under the most forcible voluntary expiration.

From these observations it is clear that, when the tonus of the body is diminished, the size of the thoracic cavity is likewise diminished. If the lungs are sufficiently deflated, some degree of atelectasis, at least in minute de-aerated areas, necessarily results: areas that are easily and quickly reinflated when the lungs are again expanded with the return of body tonus. This condition in its simple uncomplicated form has been well termed "collapse without symptoms."[8] When it is looked for, it has been found after more than 80 per cent. of all laparotomies. Doubtless the non-striated muscle-fibres in the walls of the airways also lose their tonus, like those of the alimentary canal, and such peristaltic movements[9] as they may normally have cease.

MASSIVE COLLAPSE

With the lungs partially deflated, it sometimes happens—and this occurrence is apparently one of pure chance—that mucus accumulates until one or another of the major airways is completely closed. In the lung or lobe which is thus occluded another development then sets in. The occluded gases are absorbed into the blood until the lobe or lung is completely collapsed. As one lung collapses, atmospheric pressure inflates the other lung. Hence, massive collapse is almost necessarily confined to one lung; for the collapse of one lung tends to expand the other.

The absorption of air from an occluded lung is not a physiological reaction, like the development of the atelectasis that generally precedes it. It is instead a purely physical process.[10] The sole causative condition is a plugged airway. An occluded lung is collapsed by diffusion of its gaseous contents in exactly the same manner that a lung, which has been collapsed by pneumothorax, is reinflated by the diffusion of air out of the pleural space. In both cases the gases—oxygen, carbon dioxide, and nitrogen—diffuse into the venous blood because the partial pressure of the gases in the occluded space are higher than in the blood. Blood pressure plays no part.

Relief of massive collapse requires removal of the plug, either naturally by coughing or artificially by bronchoscopy.[11] The return of tonus in the respiratory muscles—particularly the diaphragm—reinflates the lung by re-expanding the thorax. Deep breathing promotes coughing.

Normally the lungs drain freely through the airways and thus eliminate infection. In massive collapse, if the airways are not soon reopened, an occluded infection may develop and usually terminates fatally.[12] In such cases the sequence of events is: anæsthesia and operation, depressed muscle tonus, partial deflation of the lungs, blocking of a major airway, massive collapse, undrained infection, toxæmia, and death.

MUSCLE TONUS AND THE CIRCULATION

Depression of the circulation, like atelectasis and depression of general metabolism, is a common accompaniment of diminished muscle tonus. But it is only recently that it has become possible and logical to infer a causal relation between muscle tonus and the circulation. In this relation the circulation presents two closely related problems: one the converse of the other. One is the problem of how in health the normal circulation is maintained and its total flow adjusted to the varying needs of the body. The other is the problem of how in illness and vital depression the circulation fails.

Beside the heart and the vasomotor mechanism there is a third major factor in the circulation.[13] It is the factor that normally determines the volume of blood returning to the heart through the veins. It is now generally recognised that the depression of the circulation that follows surgical operations or illness is not due primarily to weakening of the heart, nor to failure of the vasomotor nervous control of the blood-vessels. It is due rather to a gradual decrease in the volume of blood returning to the heart—that is, to the progressive depression and final failure of the venopressor mechanism.

Every movement of the limbs and every contraction of the abdominal muscles tends to promote the flow of blood through the venous system back to the heart. This feature of the venopressor mechanism has indeed long been recognised. But clear evidence has only recently been developed that in the healthy body, even during complete bodily rest, the tonic contractions of the muscles maintain continually a pressure within the tissues sufficient to send a continuous stream of blood through the veins to the heart.[14] This pressure between the fibres of a muscle under tension arises in much the same way that pressure between the strands of a rope is produced by a longitudinal pull upon the rope. The pressure amounts, even in a relaxed but still tonic muscle, to 50–70 mm. of water column. When muscle tonus is increased, the pressure is higher, up to 90 mm. or more. When tonus is abolished, as it is in a moribund man or animal, the internal pressure is also abolished; *and in a dead body prior to rigor mortis it falls to zero.*

The method of measuring this tissue pressure is to thrust a hypodermic needle into the middle of a muscle, usually the biceps, and to determine the pressure required to induce a minute amount of saline to run in. During bodily rest this intramuscular pressure is too small to have any considerable direct effect upon arterial blood pressure, or to oppose *appreciably the flow of blood into a muscle.* But even in a relaxed muscle there is normally sufficient tonus to maintain the venous outflow from the muscle. It is one of the first principles of hydraulics that fluid tends to flow from a place of higher pressure to one of lower pressure; and the greater the difference of pressure the more rapid the flow. Correspondingly the higher the intra-tissue pressure the larger and more rapid the volume of the venous return to the heart; and the intra-tissue pressure *is due to the tonus of the musculature of the body,* skeletal and visceral.

These statements do not deny or question the correctness of the opinion that the entire energy of the circulation during bodily rest is due to the "push from behind" imparted to the blood by the left heart. But in order to push the blood not only from the heart to the tissues, but also onward from the tissues back through the veins to the right heart, it is essential that some of the force imparted by the left heart shall be conserved until the circuit is complete. And so long as the tissues of the body have tonus, elasticity, and an internal pressure, a part of the force imparted to the blood by the heart is retained by the blood in the vessels within and beneath the muscles. It is this force—in addition to the tonus of the capillaries [15]—that presses the blood on into the veins and thus supplies the right heart and supports the circulation. On the other hand, when muscle tonus is depressed or fails, the entire force of arterial pressure is lost in the flaccid tissues and the blood stagnates there, instead of flowing on through the veins back to the heart.

Nor is this all. When the depression of muscular tonus permits the thorax to diminish in size and the lungs to collapse toward atelectasis, another handicap is imposed upon the circulation. The negative pressure of the thorax decreases. So long as the thorax and lungs are normally expanded, this negative pressure is one of the main accessory factors aiding in drawing blood into the right heart. When the tonus of the body is diminished, not only is the positive pressure in the body as a whole diminished correspondingly, but the negative pressure of the thorax also. The effective venous pressure,[16] which is the sum of these pressures, is thus doubly decreased.

The part played by general body tonus is distinct from that of vasomotor tonus. Vasomotor tonus determines the height of arterial pressure. General body tonus determines the volume of the venous return to the heart and thus the volume of the output of the heart.[17] In progressive vital depression it is *general muscular tonus that fails first.* The venous return to the heart is thus diminished. It is only after the volume of the circulation has been thus greatly decreased that arterial pressure falls. Almost to the last the vasomotor mechanism, instead of failing, strives by an extreme constriction of the arteries and arterioles to maintain arterial pressure *in spite of the diminishing output of the heart;* then it too fails.[18] This in brief is the process of circulatory failure leading to the large majority of all deaths.

MUSCLE TONUS AND METABOLISM

The maintenance of body temperature depends upon two forms of regulation: physical and chemical. Physical regulation is effected mainly through the evaporation of moisture from the lungs and skin and through the cutaneous vasomotor adjustments. Chemical regulation is largely effected through variations in the process of combustion which affords the energy for muscular contraction and tonus. And the consumption of oxygen and production of carbon dioxide are the chemical correlatives of this liberation of energy. Muscular tonus is thus a prime factor in the chemical regulation of body temperature.

Normally, it is essential that the volume of air breathed to supply oxygen and eliminate carbon dioxide, and the volume of blood circulated to transport these gases shall be adjusted to the amount of energy liberated in the body and to the amount of material oxidised. It now becomes evident that tonus largely determines all of these processes and adjustments: the intensity of metabolism, the amount of oxygen consumed and carbon dioxide produced, the volume of blood put into active circulation through the venopressor mechanism, and the volume of respiration that will afford the amount of ventilation required for the blood as it passes through the lungs.

On the other hand, when tonus is depressed, all of these functions are depressed and thrown out of adjustment. Metabolism and heat production are diminished. Less oxygen is consumed and less carbon dioxide is produced. The venous return is decreased and with it also the output of the heart. Respiration is depressed and the lungs are partially deflated.

FACTORS INFLUENCING TONUS

The tonus of striated muscles is controlled through the motor nerve-fibres from anterior horn cells in the spinal cord. Upon these cells there are many influences: influences from the cerebrum, cerebellum, and basal ganglia—particularly the respiratory centre; influences through afferent nerves from the skin, and from the muscles themselves; and chemical influences from endocrine glands, and by the gases and alkali of the blood.

Among the influences inducing depression of tonus are anxiety, anæsthesia, particularly spinal anæsthesia, or unskilful inhalational anæsthesia and excessive relaxation—and surgical trauma.

Tonus returns fully only with recovery of vitality and health; but it is increased temporarily by frequent change of position—even turning over in bed—by strychnine and by inhalation of carbon dioxide.[19]

CONCLUSIONS

The main cause of all the depressions of function after anæsthesia and surgical operations lies in the decreased tonus of the musculature of the body.

Decreased tonus of the thoracic muscles and diaphragm induces deflation of the lungs. In extreme deflation a bronchus may become plugged with mucus. Absorption of the occluded air then produces massive collapse.

Decreased tonus of the muscles of the limbs and abdomen permits the blood to stagnate in the tissues. The venous return to the right heart is thus diminished, and the circulation is correspondingly depressed.

Decreased tonus of all the muscles of the body involves a decrease of metabolism, heat production, oxygen consumption, and carbon dioxide production. The suboxidation and acapnia may then induce further depression of many functions.

TORSION OF THE SPERMATIC CORD IN INFANCY

By G. F. Langley, Ch.M. Bristol, F.R.C.S. Eng.

SENIOR RESIDENT MEDICAL OFFICER, BRISTOL GENERAL HOSPITAL; LATE RESIDENT SURGICAL OFFICER, ROYAL INFIRMARY, BLACKBURN

Torsion of the spermatic cord is uncommon and usually occurs during adolescence and early adult life. It has seldom been recorded in an infant.

REPORT OF CASE

A. B., aged 17 weeks, was admitted to the Blackburn Royal Infirmary as a case of strangulated inguinal hernia on Nov. 19th, 1933. At the age of 2 weeks a swelling had been observed in the left groin; this was diagnosed as a maldescended testicle and no treatment was advised. The child was always fretful and undernourished, and the doctor advised surgical treatment, thinking that a coincident inguinal hernia might be the cause of the trouble. This advice, however, was rejected a fortnight before admission. On the day before coming into hospital the child cried almost continuously and vomited once. Next morning the mother noticed that the swelling appeared larger and, as the child seemed to be in pain and had vomited twice, consented to its removal to hospital. The bowels had been opened regularly each day and the vomitus had consisted of curdled milk.

On admission at 6 P.M. the temperature was 100·6° F. and the pulse-rate 140; the child was screaming with pain. Nutrition was rather poor; the tongue was clean and moist, and the abdomen was not distended or tender. A swelling was visible in the left inguinal canal, about 1½ in. long and 1 in. in diameter. The overlying skin was flushed and there was slight œdema over the external abdominal ring. Palpation of the swelling was obviously painful and disclosed a hard fixed mass which did not fluctuate and which was out of reach of the finger inserted into the external abdominal ring. There was no impulse on straining and the percussion note was dull. The testicle and scrotum were normal on the right side but the left side of the scrotum was small and no testicle was found.

A *diagnosis* of torsion of the left testicle was made on the following grounds: (1) The symptoms and general condition of the infant were not sufficiently severe to be compatible with a strangulation of 36 hours' duration. (2) The swelling was harder and more irregular than the usual strangulated hernia and it seemed unlikely that there could be a strangulation of the omentum in a child so poorly nourished. (3) The doctor had detected a maldescended testicle in the inguinal canal some months previously. (4) There were no septic foci to account for the presence of enlarged glands and clinical evidence was against an adenitis.

Operation.—Permission having been obtained for an orchidectomy the inguinal canal was exposed under ether anæsthesia. A bluish-black mass was seen in the upper part of the inguinal canal which, on dissection, was found to consist of a distended tunic vaginalis filled with blood-stained fluid. The testicle and epididymis were plum-coloured, and the spermatic cord was rotated through one and a half turns from without inwards; the highest part of the torsion was just distal to the attachment of the tunica vaginalis to the cord. Detorsion was impossible and hot packs failed to restore circulation; accordingly orchidectomy was performed. The lower pole of the tunica vaginalis was connected to the fundus of the scrotum by a thin ribbon-like band which was thought to represent the gubernaculum. A small funicular hernial sac was present but its orifice barely admitted a probe. The child made a normal recovery and was discharged on the tenth day.

Dissection of the specimen.—The veins of the cord were thrombosed above the level of the attachment of tunica vaginalis and detorsion of the cord resulted in tearing of these veins. The tunica vaginalis was enlarged and reached nearly one inch above the upper part of the epididymis so that the latter and the testis were suspended within the vaginal cavity. The testis and epididymis were engorged and were attached to each other only by a broad band running from the globus major to the upper pole of the testicle. The vessels of the cord bifurcated in this broad mesorchium to reach the two parts of the organ. Microscopical examination showed extensive interstitial hæmorrhage into the testis and epididymis; the seminiferous tubules were solid cords of cells in the centre of which there was some degree of necrosis.

ÆTIOLOGY OF TORSION OF THE TESTICLE

Scudder [1] in 1901 found 31 cases on record, 2 of these being in babies of under one year of age. Donovan,[2] in 1930, recorded 3 cases of his own in infancy and found a further 163 in the literature, in 13 of which the age was less than a year. Johnson,[3] in 1931, reported 2 cases in adolescence, and in the same year Kenneth Walker [4] described a case of bilateral torsion in a boy of 15. Muschat [5] reported 2 adolescent cases in 1931 and discussed the ætiology. Henderson and Foisie [6] reported a case of torsion of a maldescended testicle in a baby of ten months old in which a large congenital hydrocele in the opposite side of the scrotum had caused discomfort and had been relieved by tapping two months previously. The youngest case on record is that of Taylor [7] in which the nurse noticed a swelling and discoloration of the scrotum 4 hours after the birth of the infant. At operation, 48 hours later, a necrotic testicle was removed and the child lived.

Two types of torsion are described: (1) *supravaginal*, in which the whole tunica vaginalis with its contents rotates within the scrotum; and (2) *intravaginal*, in which the testis and epididymis rotate within the cavity of the tunica vaginalis. The former type can occur only after rupture of the areolar tissue binding the tunica to the scrotal wall with tearing of the gubernaculum; the existence of this type is doubted by Muschat, and Young [8] states that the condition could be caused only by severe external violence. Intravaginal torsion of the cord may occur in normally descended or ectopic testicles, but Thorek [9] found that 47 per cent. of the recorded cases were in maldescended organs. The normal testis cannot rotate owing to the firm attachment of the mesorchium to the postero-internal wall of the scrotum.

Farr [10] considered that the predisposing factors were: (1) A free-lying testis with an abnormally long mesorchium. (2) Abnormality of the relative size or position of the testis and epididymis. (3) Enlargement of the tunica vaginalis. (4) Lengthening or other abnormality of the spermatic cord. Broadening of the cord was considered to be a factor by Lauenstein,[11] and Kocher [12] noted that there was often a bifurcation of the vessels of the cord.

Muschat studied the problem by making serial sections of the cord and the cremaster muscle and then constructing models from the sections.

> It was found that, in cases of torsion, the cremaster muscle wound spirally around the cord as far as the testicle, instead of looping down over the outer side of the tunica vaginalis as in the normal specimens. He also found that the tunica vaginalis was attached higher along the cord and was enlarged, thus allowing the testis and epididymis to invaginate the sac from its upper pole. The testicle and epididymis were surrounded by the tunica and hung into its cavity "like the clapper in a bell," instead of being covered only on the antero-external surface as in normal cases. There remained, therefore, a freely suspended testicle attached by an elongated intravaginal portion of the spermatic cord to the upper part of a capacious tunica vaginalis. Contraction of the cremaster muscle would be sufficient to initiate rotation in the unstable testicle.

From these observations the predisposing factors were held to be: (1) high attachment of the tunica vaginalis along the cord; (2) testis and adnexa hang in the cavity of the tunica "like the clapper in a bell"; (3) the cremaster muscle winds spirally round the cord and can thus initiate rotation if the other factors are present.

Johnson has described cases in which a fall or coitus have been the cause of the torsion. Farr considered that the torsion might result from increased abdominal pressure in an effort, by nature, to remedy the imperfect descent of the testicle. Murray,[13] after reviewing the literature, suggested that many cases of acute strangulation had suffered from repeated attacks of recurrent, subacute torsion which had spontaneously been corrected and thus considered that most cases of torsion were of congenital origin. The testicle had many opportunities of undergoing torsion in its descent, and Murray suggested that the torsion was present at birth but that the onset of acute symptoms was due to vascular congestion associated with the period of puberty or with strain. The occurrence of torsion during sleep, as recorded in so many cases, appears to negative this view.

PATHOLOGICAL RESULTS OF THE TORSION

Putzu [14] found experimentally that torsion of 360° for 30 hours caused necrosis of the seminiferous tubules, and clinical evidence supports this finding. Venous congestion and thrombosis follow upon the damage to the thin-walled veins; exudation into the substance of the organs and into the vaginal cavity increases the stasis in the vessels; capillary hæmorrhages occur, and the delicate cells of the seminiferous tubules undergo irreparable necrosis after an ischæmia lasting about thirty hours. Rarely a superadded septic infection of the necrosed organ occurs, and may lead to peritonitis if there is an adjacent patent funicular process. Clute [15] grouped cases into (*a*) acute complete torsion and (*b*) recurrent subacute torsion. In the milder cases, about 14 per cent. of acute complete torsion, in which the vascular obstruction is not sufficient to cause gangrene he found that atrophy of the testicle occurred. Many patients have learned to correct by manipulation the recurrent subacute torsion of the testicle.

DIAGNOSIS

Constantin and Dalous[16] collected 53 cases in which a correct diagnosis had been made in 3; Thorek reports 24 cases of torsion which had been diagnosed as strangulated hernia; 15 of these were cases of ectopic testis. Most cases are diagnosed as strangulated hernia, but the degree of shock and the intensity of the gastro-intestinal symptoms are less in torsion and there is never absolute constipation. Scudder considers that in a doubtful case the absence of the testicle from the scrotum combined with an empty external abdominal ring should lead to a diagnosis of torsion rather than strangulation. Vanverts[17] states that differentiation is impossible between torsion of an ectopic testicle and strangulation of omentum in an inguinal hernia.

Donovan found that in infancy torsion of the cord may be apparently symptomless; in 2 of his cases there was no evidence of pain or vomiting, and the infants were brought for treatment because of the detection of a lump in the groin.

Differentiation has to be made, in cases of scrotal testis, from acute epididymo-orchitis, but in these the onset is more gradual and there may be confirmatory evidence such as urethral discharge, prostatitis, or a history of mumps. Inguinal adenitis may simulate torsion of an ectopic testis but can be excluded by the mode of onset and the presence of a septic focus.

TREATMENT

Detorsion should always be attempted unless there is obvious necrosis, and the application of hot, moist pads may assist in assessing the viability of the organs after untwisting. Donovan holds that orchidectomy will be necessary in all cases after torsion of thirty hours. If detorsion is possible some method of fixation is indicated to prevent recurrence, but it is doubtful if the performance of the Thorek[14] operation for fixation into the thigh would be justifiable in these acute cases. Kenneth Walker advocates exploration of the opposite testis to remedy any predisposing factors in that organ.

No fatal cases are on record.

I desire to thank Dr. Keith Cumming for permission to report this case.

THE SQUINT TRAINING CLINIC OF THE L.C.C.

BY M. THORNETT-JOHNSON, F.R.C.S. Irel.
OPHTHALMIC SURGEON, SQUINT CLINIC, PADDINGTON TREATMENT CENTRE

THE squint training clinic was started in connexion with the ophthalmic clinic of the Children's Hospital in Harrow Road in 1915. It was up-hill work because the parents did not understand that the vision of the squinting eye became lost, and, by long association, they did not realise how great was the disfigurement. The treatment too was new to them, and they disliked intensely to have the good eye covered. Few people, even among medical men, realise that marked internal squint, even with good sight in that eye, means that the squinter is in the position of a one-eyed man as regards his field of vision, which makes it dangerous for him to be in any occupation where accidents are liable to happen. I had to spend a long time explaining to each parent, and often when I had succeeded with the mother, the father refused permission for treatment. In 1917, however, the L.C.C. took over the clinic and I was able to devote myself entirely to these cases and the work went on apace as it became more generally known in the neighbourhood.

The cases are nearly all convergent concomitant squint, constant or alternating. I do not like the term "convergent," which implies a coöperation between the two eyes, whereas the exact opposite is the case. In cases of squint the power of convergence and of divergence is either absent (as in alternating squint) or deficient in varying degrees.

If one could coin a word, "abvergence" would more accurately describe the action of avoiding the object seen by the good eye. The term convergence should be confined to the action of the two eyes focussing the same object at the same instant, and in the following pages will be used in that meaning.

Children are very rarely born with a squint. The earliest in my own experience was a child brought to me at 3 months old, who was said to have squinted as soon as she had opened her eyes. The most common age is 3½ to 4 years old, but squint may occur at any age from early infancy to 6 years old. Squint acquired after this age is slight and as a rule is easily cured.

As soon as a child is seen to squint, he should be taken in hand at once; and attempts to restore the sight of the squinting eye should be made without delay. The earlier the squint occurs the greater is the loss of sight. Babies of the tenderest age can wear spectacles with safety, and after wearing them have been known to resent, in the only way open to them, any neglect in putting them on. No child is too young for treatment for the restoration of sight, and in this clinic mothers of squinting children are allowed to bring younger ones with the same defect as soon as it is seen without waiting until the child attains school age.

Before beginning treatment the willing coöperation of the child must be obtained as well as that of the parent. With this aim the mother is asked to listen while an explanation is made to the child in simple language of the meaning of a squinting eye: the loss of sight, the disfigurement, the disability it causes in later life.

His interest and ambition are awakened by telling him that unless the sight is restored and the eye becomes straight he will never be able to enter the railways, become an engineer or work in a machine-shop, drive a train, a car, or an aeroplane with safety, nor be able to become a policeman or a soldier; and in order to stimulate his present interest, he is promised a prize when the eye can read a certain line on the board. One must also show sympathy with him and praise his bravery and manliness in submitting to the discomfort of having to wear a patch, and let him realise that one is just as anxious to take it off as he is. At each visit he is commended for improvement, and if after a certain time has elapsed and none has taken place, searching questions are put as to when he "peeps" or removes the glasses. He is kindly and reproachfully reproved, reminded of the prize awaiting him, and as a rule this handling succeeds and he becomes fond of the trainer and tries to please.

Treatment

The basis of the treatment is that described by C. Worth in his book on squint. It consists of two different parts: (1) the restoration of vision to the squinting eye; (2) training the eyes to focus on the same object at the same instant.

RESTORATION OF VISION TO SQUINTING EYE.

The errors of refraction are most carefully corrected.

Where there is any loss of vision in the squinting eye, the good eye is covered by a disc of paper gummed over the lens of the spectacle, extending above to the eyebrows and across the bridge of the nose. It is unwise to cover the extreme outer field of the good eye. The child needs peripheral vision on that side in order to avoid knocking against objects he is passing. The paper projects beyond the lens so that it is difficult for him to turn his head for the use of that eye in direct vision. The complete covers supplied by opticians and advised by some surgeons are dangerous, as well as depressing to the spirit of the child.

The paper is renewed every week and the vision taken until the sight reaches 6/9. It is then replaced by a film of shaving soap rubbed over the lens. By this time the vision of the squinting eye is so useful that there is little inclination on the part of the child to use the good eye. The soap is kept on until the squinting eye can "fix"—i.e., the patient can use that eye to focus an object with both eyes uncovered and *without spectacles.* The question of fixing is more important than that of vision, for in some cases of bad scotoma the vision never arrives at 6/6, and if the good eye is kept covered beyond the stage of fixation the vision of the good eye may deteriorate, and actually become the squinting one, while the other may still not improve to normal. A girl of 5 who had so little vision in the squinting eye that she could not see fingers at the distance of one foot, and a very large central scotoma, had the sight restored until that eye apparently became the fixing one at will, the other going into the corner. The child was most unreliable, and it was difficult to find out her distant vision but she could read Ji. It is probable that the scotoma has not entirely gone and that she uses a portion of the retina at the inner side of the yellow spot. If further covering were done now, the good eye would lose its vision without corresponding improvement in the other.

Some ophthalmic surgeons claim that training should begin when vision is so much as 6/12, and that the sight is thus more quickly restored. I have not found this to be so *unless the eye can also fix.* When using the amblyoscope the weaker eye loses the object and the child carries on only with the good eye. This is the cause of many cases of faulty projection which rarely occurs unless the sight of the bad eye is less than that of the good one, or cannot fix; or again in cases of bad alternating squint.

Moreover if training is carried out when there is a loss of one image (constantly in the same eye) this image has to be continually illuminated more brightly than the other, involving the use of artificial light, which is quite unnecessary if the standard of a "fixing" eye is adhered to.

Certain cases of children of 10 and upward who are unable to spend the time from lessons in regaining the sight of the eye may lose the squint by training to the point of absolute cure, but the vision does not improve in the same ratio. Two little girls, twins of 11, with marked internal squint and vision of 6/60 and 6/36 respectively, kept the patches over the good eyes until the bad ones obtained 6/24 and 6/18 respectively. Then they felt unable to continue on account of their school work. The patches were removed and the children have had training for several months. There is now no squint either with or without glasses, but the vision of the first girl is now only 6/24, that of the second 6/12.

Children with central scotoma and vision very much less than 6/60 cannot be treated with much success after they are 6 years old. They improve, and if it were possible to ensure that the treatment was being really carried out, I believe one could gain success with children older than this. But it is a very trying and long treatment for a child of that age, and would require so much supervision that it is impossible with the children of the clinic.

Some surgeons allow the child to wear the patch only half the day. I have found this to be almost useless. The great difficulty is to get the child used to wearing it; if he does this constantly he becomes accustomed to it and ceases to fret; but when it is removed every day, a constantly repeated irritation occurs, and the temptation to "peep" proves irresistible. Moreover the necessity for wearing it is discounted, not only by the child, but also by the parents and teacher who become impatient of the much more prolonged treatment.

Where there is no scotoma and a vision of 6/60 it is amazing how much children improve up to the age of 9 or even 10 years of age.

I have just discharged a boy who was 9 years and 10 months old with a vision of 6/60 when he first came. He arrived at 6/6 with entire disappearance of the squint in ten months. Another boy of 9 improved from 6/60 to 6/6 in six months.

Training should be thoroughly done even if the squint has disappeared in these cases, because the habit of using one eye only is so ingrained that they must be taught to use the eyes together, and frequent tests of the vision must be taken in case of loss. The custom of the clinic is to "soap" between the weekly training until the habit is broken.

Time taken to restore sight to the defective eye.—During the first seven years of the clinic children with no central vision and seeing less than 6/60 took on an average 21 months to restore vision to normal. One case took 3 years and the shortest time was 6 months.

In the later years of the clinic this average was reduced to 18 months, an improvement I put down to the greater knowledge of the parents of the treatment, and perhaps also to my own added experience. The average for children with 6/60 or better vision has been as follows:

Vision.	Average time.	Vision.	Average time.
6/60	13 months.	6/24	9 months.
6/36	12 ,,	6/18	7 ,,

Those with better initial vision were improved to normal in correspondingly less time.

There are no failures with this treatment provided it is well carried out, and of course with due regard to the age at which the treatment is begun. The clinic was started with the desire to find out how far it is necessary to limit the age of the child at which treatment can be undertaken with success, and experience has shown that pessimistic forecasts are quite unjustifiable.

TECHNIQUE OF TRAINING

The technique of training the eyes to focus on the same object at the same minute may be divided into 3 parts: (*a*) acquiring of binocular vision (B.V.); (*b*) training of con- and divergence; (*c*) acquiring of stereoscopic vision.

Acquiring Binocular Vision.—When the sight of the squinting eye has been made equal to that of the straight one, or is able to fix, the power of binocular vision is investigated by means of the amblyoscope. The first series of pictures consists of, for example, a bird on one slide and a cage on the other, and the like. By moving the arms of the amblyoscope the pictures advance towards one another until they coincide so that the bird is seen as if inside the cage. When the child sees the bird in the cage, both eyes are then focused on the same spot and binocular vision *at that point* has been obtained, both eyes turning towards the nose at the same angle. When this stage has been reached, the eyes have to be taught to adduct and to abduct at the same time and equally.

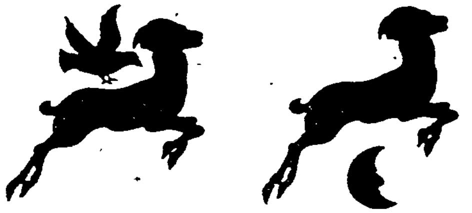

FIG. 1.—Series 2 A. For horizontal deviation.

Training of Con- and Divergence.—For this purpose the second series of pictures has been devised (see Fig. 1). Each pair has a large central figure, such as a goat, a horse, an engine, while above one figure is a smaller object, such as a bird, and below its pair is a dog, &c. When the two central images coincide only three objects are seen, the central image with the smaller figures above and below. These small ones should be very definite and compact in outline so that when the arms of the amblyoscope move to and fro, they tend to keep the two central images as one, thus developing the power of true con- and di-vergence.

Both these movements are deficient in this form of squint but it is better to begin with the training of convergence; it is easier and more effective. Binocular vision having been obtained, the child saying he sees one goat, with a bird above and a moon below, the arms of the amblyoscope are slowly and steadily pressed together, while the trainer urges the child to keep the bird and the moon in position above and below the goat. He must be constantly questioned as to what he sees, and the questions must be changed in form, in tone of voice, and in manner, so as to prevent the child from answering mechanically. When making these questions one must have a very definite knowledge of what the child sees, and be on the alert against being deceived, for with the best will in the world to speak the truth, the child may deceive unconsciously. Moreover the eyes tire quickly and must have frequent rests. Ten minutes at the most is all that can be done while the child is honestly striving to keep the images together, and one must be on guard that the tired eye does not go in (and produce "faulty projection") while still the child continues to give apparently satisfactory answers. One would imagine that where the eye goes in, one's first effort would be to separate the eyes by moving the arms apart, but it will be found that making the eyes truly converge gives much better results than attempting to make them diverge Force convergence and in a short time divergence may be begun.

Fatigue, both ocular and mental, is a reason for not allowing the child to handle the amblyoscope himself, especially in the second series of slides. In the first series, that of putting the bird into a cage, convergence and divergence are not practised and there is no possibility of the child not understanding what is to be done, nor of doing it in the wrong way, nor is it tiring. Where binocular vision is absent, and this especially in alternating squint with no loss of vision, one can give the amblyoscope to the child and let him try for half an hour at a time. He must be made comfortable, sitting lower than a table on which he can rest the elbows. The eyes do not get tired because there is no training of the act of convergence, merely that of binocular vision in one particular position.

Where there is an upward squint as well as an inward one, the best slides have a vertical central figure, such as a tree, upright line, or a pillar-box, with a figure on opposite sides of each pair of slides (see Fig. 2). This obviates raising or lowering one arm of the amblyoscope or its corresponding picture, and causes the errant eye to come down to its proper level.

After con- and divergence have been trained to the fullest extent with a range of quite 90 degrees as gauged on the scale of the amblyoscope, stereoscopic slides are shown, and the patient is carefully questioned as to what he sees. One must, in this as in the second series, get into the mentality of the child and realise in one's own mind what he is seeing. On obtaining stereoscopic vision, the eyes are straight when looking through the amblyoscope, but may revert to the bad position the instant it is taken away. This is especially the case with alternating squints when B.V. was absent at first, and was attained with great difficulty. One of my worst failures was a girl of 5, with good vision in each eye and an extreme squint in either alternately. It took three years before she could get the bird in the cage, but after that she obtained a great range of convergence, and stereoscopic vision, so far as one could determine; but the squint was nearly as large when she left at the age of 14 as when she came. This was a case on which I was very anxious to have an operation; unfortunately the child was terrified and has steadfastly refused, but there seems little doubt that after this training the result would be a great success, although these are the very cases which are so difficult to cure by operation if there has been no preliminary training.

Alternating squints, with very little or no error of refraction and good vision in either eye, are the most difficult. They have usually no B.V. and it may take years before this can be obtained and when advanced to the second series may acquire an immense range of true con- and divergence; while working with the amblyoscope, the eyes appear to be perfectly straight, but immediately go back to the old position on ceasing to do so. If these children are seen daily, a month or two makes a rapid improvement in the position of the eyes, but these children only attend once a week, and frequently miss even that, while holidays cut down the attendance to only nine months in the year. Operation after training in these cases has been most successful and I advise it whenever the squint persists after full con- and divergence and stereoscopic vision have been acquired.

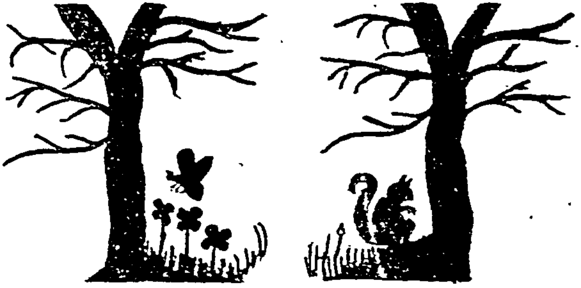

FIG. 2.—Series 2 B. For both horizontal and vertical deviation.

The treatment by amblyoscope is not as easy as it sounds. It requires a very long experience of many cases and immense patience and understanding; also a knowledge of the infinite mistakes and misunderstanding to the child is liable. Cases with good B.V. and convergence are easy and require no great skill on the part of the surgeon. But children with no B.V., who lose first one image and and then the other, and in the second series cannot get any range of con- and divergence have to be helped by the surgeon's understanding of their difficulties, by special ways of showing the pictures and of moving them to and fro, and by judgment of what the child is really seeing, no matter what he says.

The large instruments with electric light and coloured pictures and with innumerable gadgets for moving separately the arms in different directions are nothing more than glorified amblyoscopes and are not more efficient than amblyoscopes properly used, and a good many of the gadgets are not at all necessary. The pictures are not artificially lit in my clinic, and the arms of the amblyoscope need have no separate movement if the pictures I suggest are used. But the more elaborate instruments have many advantages. The children like the coloured pictures, and are more interested in them. The position of the eyes is better shown, and the surgeon is not obliged to assume a cramped position nor to hold the instrument for the child to look through. I find too that the ordinary amblyoscopes quickly become maladjusted; one arm may be higher than, or twisted slightly in relation to, the other. When using it, the surgeon should look through it himself before showing it to the child. The larger instruments, being more fixed, have not these defects. I should like to suggest that a much simpler form might be made with fewer gadgets, which would be equally effective and not so expensive. The simpler and cheaper they are the better, since the establishment of squint-training clinics in every district where there are many children is greatly to be desired. Ordinary stereoscopes are of no use whatever until the child has obtained stereoscopic vision with the amblyoscope. The same may be said of choreographs, but these supply an interest and change for the children and are useful in that way.

When the eyes are straight (i.e., no squint when the glasses are removed) and good con- and divergence have been obtained as well as stereoscopic vision, the child is discharged for six months. He is then called up again, and the eyes examined for loss of vision, or squint, or loss of ability in amblyoscopic exercise. If these are normal he is discharged for a year, and at the end of that time, if there has been no retrogression he is discharged permanently. Sometimes the sight may have gone back, but a few weeks or months of "soaping" brings the vision to normal again, and he is given another course of training. When this is satisfactory he is discharged for another six months, but not permanently until a year has elapsed without any retrogression. For training it is not so necessary to begin at an early age as it is for the restoration of vision, for cases of cure have occurred when training has been begun as late as 13 and 14, while certain adults gain great benefit from it. I consider the best age to begin in alternating squints is about 8 years old, but where sight has been restored in the squinting eye, training should follow on such restoration without waiting.

Results

The results tabulated in Table I. are taken from current and past records of patients treated in the clinic since 1924. Unfortunately most of the records of discharged patients was lost during 1928.

The results tabulated in Table II. are taken from short private notes of cases of which fuller records are among those lost and are therefore set out in less detail.

Results in 210 *cases dating from* 1924

1. Straight on restoration of vision	41	(19%)
2. Straight after training	113	(53%)
3. Straight with glasses, slight squint* without ..	17	(8·1%)
4. Slight squint with glasses	13	(6·2%)
5. Much improved	20	(9·5%)
6. Slight improvement or failure	6	(3%)

Children who did not attend for training, or attended so seldom that no effect could possibly result have not been included in the tables.

Group No. 1, although straight on restoration of vision, were found to have great deficiency in the power of convergence, and had a training of a few months only to develop this. Groups 2, 3, and 4, nearly all constant squints, took an average of 11·9 months of squint-training. Groups 5 and 6, were all alternating squints and constituted 13·3 per cent. of the whole; and the time taken in their training averaged 32·3 months.

Some of the patients were very irregular in their attendance and one month may represent only one or two treatments instead of the four or five among the regular attendants. The alternating squints were on the whole more regular in attendance than the others.

Results in 255 *cases dating from* 1915 *to* 1922

1. Straight after training and restoration of vision	171	(67·02%)
2. Slight squint	48	(18·8%)
3. Much improved	28	(11%)
4. Failure	8	(3%)

Among the 8 failures was a family of 4 whose parents both squinted and the whole family was of very low intellect.

The work of the clinic goes to prove that in squinters the centre controlling the power of true convergence of the eyes is deficient. When it is quite undeveloped, alternating squint occurs early in life and training must be carried out until the eyes can converge before any operation should be done. In constant squint there is less deficiency in the centre, and training has been successful in curing most cases. If the squint does not entirely disappear it is reduced to quite negligible proportions.

Any kind of illness, injury, shock, fright, operation, or strain, whether mental or physical, will cause a squint in those with a deficient coördinating centre. I have not found a case of squint occurring after an illness without this deficiency or a very large error of refraction. During treatment, an accident or illness may be most detrimental to the progress already made.

A boy of 5, who had a high error of refraction, and a very large squint, had the sight of the bad eye restored from 6/60 to 6/6 with loss of the squint except occasionally on removing the glasses. He was knocked down by a car, and on his return to the clinic after some weeks in hospital, the squint had returned, he had lost binocular vision and could do none of the exercises. His mother then became impatient and he was taken to a hospital. Even the removal of teeth under an anæsthetic may be followed by severe retrogression.

The feature common to nearly all the children of the clinic is the habit of mouth-breathing. It is rare to have a normal nose-breathing child brought with a squint, and those that are are usually the true alternating squints with a very deficient centre. Moreover, until the child has learnt to keep the lips closed it is very difficult to get rapid improvement in vision, and afterwards to increase the range of convergence. Consequently an important part of the treatment consists in curing this habit. The consequences to the general health and appearance, are pointed out to both mother and child, and in very bad cases, a prize is promised if the child learns to keep his mouth closed. In most this habit is thus cured, although the children are seen only once a week or even less. Operation for enlarged tonsils and adenoids is not advised unless these are septic, because of the bad effect operations have on the progress of the case. When the child learns to keep the mouth shut, the adenoids and enlargement of the tonsils usually disappear. I am convinced that the ill-health, the susceptibility to infection, the frequent colds, bronchitis, and cough, the chronic laryngitis and nervous irritability associated with the mouth-breathing habit are very potent direct causes of squint.

---

* Slight squint is one which is not seen without special examination, and to the laiety appears to be straight.

ALKALOSIS ARISING IN TREATMENT OF PEPTIC ULCER

By Wilfrid Oakley, M.D. Camb., M.R.C.P. Lond.
CHIEF ASSISTANT TO A MEDICAL UNIT, ST. BARTHOLOMEW'S HOSPITAL

The use of large doses of alkali in the treatment of peptic ulceration was first described by Sippy[1] in 1915, since when alkalis have held a prominent place in the treatment of this condition and of dyspepsia in general. The occurrence of certain symptoms associated with a raised alkali reserve was observed in some of Sippy's cases by Hardt and Rivers,[2] who in 1923 published the first clinical account of uncompensated alkalosis, recording 16 cases. The clinical picture and chemical findings were fully described in 1932 by Cooke[3] whose 9 cases brought the total on record to 68.

From these introductory remarks it would appear either that alkalosis is rare or that it often passes unrecognised. The object of this paper is to suggest that the second explanation is probably the correct one, and further to draw attention to certain features of alkalosis which in previous accounts have been omitted or insufficiently emphasised.

The present series of 7 cases, collected from the wards of a general hospital, shows the necessity of keeping in mind the possibility that alkalosis may develop in any case taking alkalis regularly, even in moderate doses. Although the dosage of alkali does not vary greatly in the different wards, no less than 5 of these cases were diagnosed by one physician or his assistants, who were on the look-out for the condition, and it is therefore probable that many cases pass undiagnosed, either to recovery or (more probably) to death.

Alkalosis is said to be commoner in men than in women, and of the 7 patients no less than 6 were men.

SYMPTOMS AND SIGNS

Symptoms are both numerous and varied, and are rarely if ever all seen in any one patient or even series of patients. The most characteristic are anorexia, headache, irritability and changes in mentality, nausea, vomiting, aching pains and twitching in the muscles of limbs, and weakness which may amount to prostration. Flushing and perspiration may be present, and, in severe cases, slow respiration-rate, rapid pulse, tetany, and even fits may precede the onset of coma which is usually fatal, the patient dying uræmic.

The headache is characteristic, and is described by the patient as a sensation of weight on the top of the head. The mental changes also deserve brief mention owing to their lack of uniformity; most patients become aggressive and difficult to manage, while others (as in Case 2 below) are confused and disorientated. Case 1 is interesting in this connexion because the first sign of his condition was recognised by the ward sister, who noted the patient's inability to keep his bed tidy.

Tetany, even in latent form, was not observed in this series, but in Case 4 there were two fits, in one of which the tongue was bitten, the reflexes remaining remarkably brisk.

Physical signs.—The patient may be flushed and respiration shallow, but these signs are often absent, and were not noted in any of the present cases. The tongue is dry and furred, and, apart from muscular tenderness and urinary changes, the principal signs are those of increased neuromuscular excitability; these include brisk reflexes, muscular twitchings, and occasionally latent or frank tetany with carpopedal spasms.

Incontinence may complicate severe cases, and occurred for a short time in Case 1. The urine is typically increased in amount, alkaline in reaction, and contains protein and granular and hyaline casts, red and white blood-cells being common but less constant findings. The amount of protein is usually small, but quite large amounts may be present, as in Case 1, and the urine may resemble that of acute nephritis.

CHEMICAL FINDINGS

The alkali reserve is raised from its normal range of between 55 and 75 c.cm. of CO_2 per 100 c.cm. of plasma to 100 c.cm. or even more, the highest value recorded below being 93·2 c.cm. in Case 1. The blood-urea and non-protein nitrogen are also raised in all cases of recognisable alkalosis, and may reach the exceedingly high figures of true uræmia. The chloride content of both blood and urine was found by Cooke to be diminished, but was not estimated in the cases described.

THE CASES

The full list of alkalis used in the treatment of these patients includes magnesium oxide and carbonate, sodium citrate and bicarbonate, calcium carbonate, and bismuth oxycarbonate. As these drugs were given in mixtures of varying composition and dosage it has been decided, for the sake of simplicity, to state the form of alkalis used in each case, and express both the total and average daily intake in terms of grammes of sodium bicarbonate.

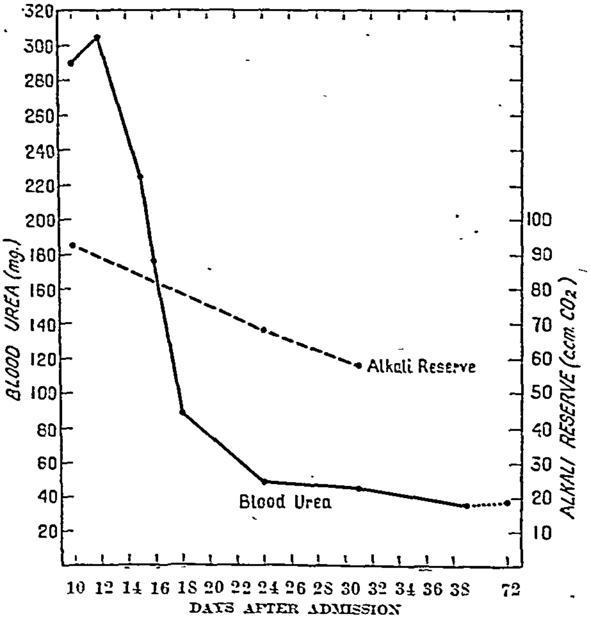

FIG. 1 (Case 1).—Blood-urea (mg. per 100 c.cm.) and alkali reserve (c.cm. per 100 c.cm.) from day of onset of alkalosis.

Case 1.—Male, aged 30. This patient was admitted on account of hæmatemesis, with only three weeks' history of epigastric pain which was continuous and unrelated to food. Hæmatemesis was preceded by melæna on two consecutive days. Examination was entirely negative except for marked anæmia, the hæmoglobin being 54 per cent. Treatment consisted of a modified Lenhartz diet and alkalis. Nine days after admission, after three days' constipation, the patient was seen to be sleeping with his eyes open. Next day restlessness and inability to keep the bedclothes tidy were noted by the sister of the ward, and the same night the patient insisted on getting out of bed to pass urine. This was followed by incontinence of urine and fæces, and alkalis were discontinued. The blood-urea was 290 mg. per 100 c.cm., and the alkali reserve 93·2 c.cm. CO_2 (Fig. 1). Drowsiness and dryness of the tongue were present, and the urine contained protein and occasional red cells, but no casts, and the blood pressure was slightly raised. Ammonium chloride was given for two days in doses of 20 grains four-hourly, but had to be stopped because of a mild colitis. The patient rapidly improved, but eight days after the onset of symptoms granular casts appeared in the urine which had the characteristics of a mild attack of acute nephritis. Red cells and casts persisted for two months, at the end of which the patient had lost all symptoms of both peptic ulcer and alkalosis. X ray evidence of ulcer was never obtained.

Alkalis (powder) ..	Magnesium oxide, sod. citrate and bicarb., and bismuth oxycarbonate.	
Total intake ..	321·6 g. sod. bicarb.	
Average daily intake	40·2 g. ,, ,,	for 8 days.

CASE 2.—Male, aged 38. This patient gave ten months' history of hæmatemesis and epigastric pain unrelieved by alkalis. A month before admission the patient began to vomit, and X ray examination showed the presence of a gastric ulcer. The only abnormality discovered on examination was epigastric tenderness and rigidity. Treatment consisted of modified Lenhartz diet and alkalis, and after one week vomiting occurred daily, the patient complaining of anorexia and a dry mouth. *On the tenth* day, after four days during which the bowels were only opened once, the patient became mentally confused and disorientated, and complained of a sense of pressure on the top of the head and pain in the leg muscles, which began to twitch so that he could not keep his legs still. Alkalosis was diagnosed, and the alkali reserve and blood-urea were estimated, the former being 92 c.cm. CO_2, and the latter 118 mg. per 100 c.cm. (Fig. 2). The urine was strongly alkaline, and contained occasional red cells and epithelial and hyaline casts. Alkalis were discontinued, and acid sodium phosphate was given in doses of 30 grains three times daily with rapid relief of all symptoms except the pain in the legs, which continued for a further two weeks.

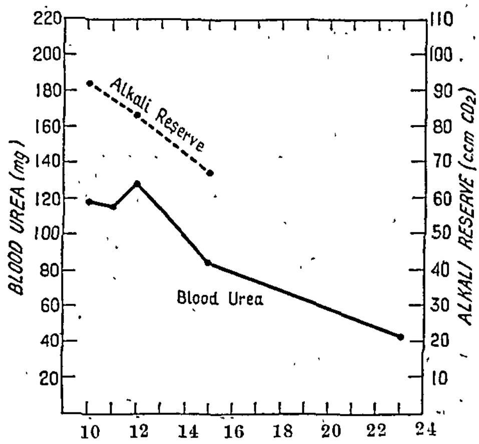

FIG. 2.—Blood-urea and alkali reserve, in Case 2, from day of onset of alkalosis.

Alkalis (powder) ..	Magnesium oxide, calcium carb., sod. citrate, and bismuth oxycarbonate.	
Total intake ..	437·1 g. sod. bicarb.	
Average daily intake	43·7 g. ,, ,,	for 10 days.

CASE 3.—Male, aged 63. In this case there was only one week's history of giddiness and melæna without abdominal pain at any time. Physical examination was negative except for signs of severe anæmia (hæmoglobin 38 per cent.). The urine was normal. Treatment consisted of modified Lenhartz diet, citrated milk and alkalis on which the patient improved for three days. On the fourth day the pulse-rate rose without evidence of renewed bleeding, and alkalis were stopped. On the following day the patient developed parotitis and became irrational. On the sixth day after admission the blood-urea was found to be 140 mg. per 100 c.cm. and the alkali reserve 68 c.cm. CO_2. A blood transfusion was given without improvement, the blood-urea rose to 225 mg., muscular twitchings developed, and the patient died in coma eight days after admission. During the whole period the bowels were only once opened without enemata, which were given on two occasions. Examination of the urine could not be carried out because of incontinence.

Post mortem the kidneys appeared to be normal to the naked eye. On microscopical examination the glomeruli were normal, but the tubules were seen to contain small quantities of lipoid, the tubular epithelium being rather swollen. No other abnormalities were seen.

Alkalis (powder) ..	Magnesium carb., sod. bicarb., and bismuth oxycarb.	
Total intake ..	90·2 g. sod. bicarb.	
Average daily intake	22·5 g. ,, ,,	for 4 days.

CASE 4.—Male, aged 47. This patient gave a typical history of peptic ulcer over a period of five years with melæna for three weeks before admission. Radiography showed a duodenal ulcer. The only abnormal physical signs were epigastric tenderness and rigidity. Treatment was similar to that in the previous cases, and the patient improved for about a week when he began to vomit. He vomited five times during the sixth and seventh days after admission, and on the eighth, after four days' constipation, suddenly had a fit without aura or obvious tonic or clonic stages. There was no foaming or involuntary micturition, but the tongue was bitten and the reflexes were subsequently found to be very brisk. The urine was normal. Later on the same day a second fit occurred, similar in all respects to the first. Next day the patient was drowsy, his tongue was moist, but headache, muscular pains, and twitchings were absent. The alkali reserve was not determined, but the blood-urea was found to be 142 mg. per 100 c.cm. The urine now contained granular and hyaline casts, but no blood or protein, both of which appeared in small amounts during the next two days. Alkalis were discontinued, and five days after the onset of fits the patient had greatly improved, the blood-urea having fallen to 64 mg. Ten days later the blood-urea was 36, and X rays showed no evidence of ulcer.

Alkalis (powder) ..	Magnesium oxide, sod. bicarb., and calcium carb.	
Total intake ..	438·8 g. sodium bicarb.	
Average daily intake	54·8 g. ,, ,,	for 8 days.

CASE 5.—Male, aged 30. This man gave a typical history of peptic ulceration extending over five years, with hæmatemesis and perforation four years previous to admission. On examination the only abnormal signs were tenderness and rigidity in the epigastrium. The urine was normal. The patient was treated conservatively with diet and alkalis in a surgical ward for seventeen days with relief of pain. Vomiting now became more frequent, the blood-urea was found to be 60 mg. per 100 c.cm., and alkalosis was diagnosed. Alkalis were discontinued, and acid sodium phosphate given in doses of 30 grains three times a day for one day, after which the patient was transferred to a medical ward. During the next two days he developed anorexia, became gloomy and depressed, and complained of a sensation of heaviness in the head. Constipation was marked during this period and for the next nine days, during which the bowels were only once opened naturally. The tongue was dry and furred, but pains in the legs and muscular twitchings were absent. The blood-urea was 60 mg. per 100 c.cm.; the alkali reserve was not determined. The urine at this stage was alkaline and contained granular and hyaline casts, but no albumin or blood. *During the next* five days the blood-urea rose to 100 mg., the urea clearance being only 43·5 per cent. of normal. During the first week following his transference to a medical ward the patient received no acid, and was actually given a drachm of alkaline powder on eight occasions because of abdominal pain. At the end of a week all alkali was withheld, but the patient continued to be irritable and difficult, the tongue remaining dry and a trace of albumin being present in the urine. The blood-urea fell slowly during the next fortnight, at

the end of which it was 65 mg. with a urea clearance of 68 per cent. of normal. One week later the patient was transferred back to a surgical ward because of persistent pain and vomiting, and a partial gastrectomy was performed with considerable difficulty owing to adhesions, two days after which he died of peritonitis. There was no post-mortem examination.

Alkalis (powder) ..	Magnesium oxide and carb., calcium carb. and sod. bicarb.	
Total intake ..	654·4 g. sod. bicarb.	
Average daily intake	36·4 g. ,, ,,	for 18 days.

November	9	12	15	18	21	23
Blood-urea in mg. per 100 c.cm.	60	72	100	70	50	65
Blood-urea clearance per cent. normal	—	—	43·5	—	—	68·0

CASE 6.—Female, aged 76. This patient had suffered for two months from pain after food, anorexia, and vomiting. There was a history of cerebral thrombosis 2½ years previously. Examination was negative except for severe anæmia (hæmoglobin 57 per cent.). The stools were positive for occult blood, but radiography revealed no ulcer. The patient was treated with a modified Lenhartz diet and alkalis, and improved except for frequent vomiting until one month after admission, when she developed retention of urine, and had to be catheterised. At the same time the patient's mental condition was noted to be strange, and she vomited twice. As in the other cases the onset of symptoms was preceded by a period of obstinate constipation necessitating digital removal of hard fæcal masses. Alkalosis was suspected and alkalis discontinued. The blood-urea was found to be 95 mg. per 100 c.cm., but the alkali reserve was not determined. Large doses of acid sodium phosphate were given, and the blood-urea fell to 64, but rose again two days later to 72 with the onset of hæmaturia which was possibly due to excessive acid. One week later the blood-urea had again fallen to 40, the blood-urea clearance being 74·7 per cent., but hæmaturia persisted. The patient returned home at her own request.

Alkalis (mixture) ..	Magnesium oxide, sod. citrate and bicarb., calcium carb., and bismuth oxycarbonate.	
Total intake ..	748·1 g. sod. bicarb.	
Average daily intake	23·4 g. ,, ,,	for 32 days.

CASE 7.—Male, aged 64. This patient was admitted for abdominal pain which had persisted for five years with attacks of vomiting. On examination there was epigastric tenderness and rigidity and severe anæmia (hæmoglobin 30 per cent.). Occult blood was present in the stools. The patient was put on a modified Lenhartz diet and alkalis, and after eleven days became flushed and mentally deranged, restraint being necessary to keep him in bed. Next day the patient was comatose, with a dry furred tongue and Cheyne-Stokes respiration. The urine was normal. The coma deepened, temperature rose suddenly to 106° F., and the patient died three days after the onset of symptoms. During the last eight days the bowels were only once opened, and then with an enema. As the diagnosis of alkalosis was not made until forty-eight hours before the patient's death alkalis were continued up to this time, and the alkali reserve was not estimated, but the blood-urea one day before death was found to be 250 mg. per 100 c.cm.

Post-mortem examination showed a small gastric [illegible] which appeared to be healing. Macroscopically [illegible] kidneys were normal except for slight reduction [illegible] while microscopic examination showed only [illegible] fibrosis, occasional arterio-sclerotic changes, [illegible] small calcareous deposits.

Alkalis (mixture) ..	Magnesium oxide, sod. [illegible] carb., and bismuth [illegible]
Total intake ..	540·5 g. sod. bicarb.
Average daily intake	38·6 g. ,, ,, [illegible]

DISCUSSION

Cases 1 and 2 may be considered [illegible] of alkalosis with raised [illegible] urea. The most interesting features are the persistence in the former of the urinary changes, and in the latter of muscular pains in the legs, for a long while after the other symptoms and signs had disappeared. In Case 3 the alkali reserve was only 68, but as alkalis were stopped two days before this determination was made it is reasonable to suppose that it had probably been much higher. The muscular twitchings, severe constipation, and high blood-urea, in the absence of any pathological changes in the kidney, can best be explained as due to alkalosis, and the amount of alkali taken is at least compatible with such a diagnosis. In the remaining four cases the alkali reserve was not determined, and the diagnosis therefore rests on the clinical picture, the blood-urea findings, and (in Case 7) the absence of pathological changes in the kidneys.

In Case 4 the sudden onset of fits and drowsiness with the appearance of casts in the urine, all of which disappeared after the stopping of alkalis, puts the diagnosis of alkalosis beyond reasonable doubt. The rise and fall in blood-urea which paralleled the onset and disappearance of the clinical manifestations is typical of the condition under consideration. Cases 5 and 6 may be looked upon as mild but definite examples in which the clinical picture and raised blood-urea can best be explained as being due to the large amounts of alkali they are known to have received. The diagnosis in Case 7 was not suspected until just before death, and is based on the absence of any evidence of kidney disease in a patient who was receiving large doses of alkali, and who died comatose [illegible] a high blood-urea. While the evidence is [illegible] stantial it was considered sufficiently [illegible] alkalosis to admit of inclusion in the [illegible]

Analysis of these cases reveals [illegible] in common. In all of them the onset [illegible] was preceded by several days' obstinate [illegible] Apart from any direct relationship [illegible] between constipation and the [illegible] is possible that there may be [illegible] connexion between the [illegible] magnesium oxide or carbonate [illegible] cases of peptic ulcer as a [illegible] constipation without [illegible] more drastic purges [illegible] in 2 of the above [illegible] high alkalinity [illegible] determine the [illegible] that [illegible] all the [illegible] for the [illegible] average [illegible]

[illegible] life [illegible] one [illegible] pieces [illegible] apped [illegible] been [illegible] spital. [illegible] wenty [illegible] fully [illegible] memo larger doses of alkali being taken in the form of powder than are prescribed, because of variations in the size and degree of filling of the spoon used. This source of error has been excluded as far as possible as a causative factor in the cases described, but is one seriously to be considered and guarded against when prescribing alkaline powders to out-patients.

The total amount of alkali taken depends on the period of administration, and is therefore less instructive than the average daily intake. The former, expressed in terms of grammes of sodium bicarbonate, varied between the wide limits of 85·3 and 917·1, the average being 493·2, while the latter, similarly expressed, ranged between 21·5 and 54·8 with an average of 38·1.

In one case the daily intake exceeded 50 g., in two 40 g., in two 30 g., and in two 20 g. While it is impossible to draw conclusions from so small a number of cases it seems possible for alkalosis to develop on relatively small doses of alkali, although it must be admitted that, of the patients receiving only about 20 g., one (Case 6) was an elderly woman with arterio-sclerosis and mild symptoms of alkalosis, while in the other (Case 3) the diagnosis is open to doubt.

It is well known that vomiting tends to produce alkalosis, and, in Case 6, the frequent vomiting (twelve times in fourteen days) which immediately preceded the onset of alkalosis may help to account for its occurrence on such relatively small dosage of alkalis. It is of interest in this connexion to note that the sudden onset of fits in Case 4 followed two days of repeated vomiting. In the remaining cases, however, vomiting was not a marked feature.

The reason why alkalosis develops in some patients and not in the majority treated with equally large doses of alkali is not known, but may be due to a failure on the part of the kidneys to excrete alkalis. It is known that damaged kidneys are particularly susceptible to alterations in the hydrogen-ion concentration of the blood either towards the acid or alkaline side, the range of optimum renal function being considerably restricted, but in none of the cases recorded was there any clinical evidence of previous renal disease, and in the two which came to autopsy no pathological changes of significance were discovered.

Treatment.—Severe degrees of alkalosis can always be prevented if the existence of the condition and the nature of its clinical manifestations are remembered, the bowels of all patients receiving large doses of alkali kept well open and magnesium salts given with reasonable discretion. In any suspected case all alkalis should be withheld, and the alkali reserve and blood-urea estimated without delay. If these are raised, acid should be given in the form of ammonium chloride or acid sodium phosphate, the former in doses of grs. 15–20, and the latter grs. 30–40, three times a day after food, until the alkali reserve, which should be estimated daily, or at least every two days, has returned to normal limits. The protein intake should be limited to about 40 grammes a day, and all food given in fluid or semi-solid form, careful attention being paid to the condition of the mouth and bowels.

Treated along these lines all but the most severe cases should recover, but symptoms such as pains in the legs may persist for several weeks. It is unwise, however, to perform any operation until the blood-urea has been normal for some days.

CONCLUSIONS

The treatment of peptic ulcer by alkalis and diet is occasionally complicated by the occurrence of certain symptoms associated with urinary changes and a rise in the alkali reserve and blood-urea. These symptoms are preceded by a period of marked constipation and, if untreated, may lead on to coma and even death in uræmia. The amount of alkali required to produce alkalosis is usually large, being equivalent, in the 7 cases here recorded, to about 40 grammes of sodium bicarbonate a day; but symptoms may result from smaller doses, especially if there is severe or continued vomiting. The prognosis in cases recognised in the early stages and suitably treated is good, but in the late stages the patients may die in spite of treatment.

I wish to thank the honorary physicians of St. Bartholomew's Hospital for their kind permission to report on cases under their care, and especially Dr. George Graham for much valuable help and criticism.

Clinical and Laboratory Notes

A CASE OF PNEUMOCOCCAL MENINGITIS

BY DUNCAN LEYS, D.M. Oxon., M.R.C.P. Lond.
PHYSICIAN TO SELLY OAK HOSPITAL, BIRMINGHAM

THE typing of the pneumococcus in cases of meningitis is not undertaken sufficiently often, as a routine, for figures to be available for a large series. Of 11 cases occurring among adults at Selly Oak Hospital during the last two years, all associated with pneumonia, the pneumococcus belonged to Type I. in 9, to Type II. in 1 (in which otitis was also present), and to Group IV in 1 which followed trauma at the base of the skull. All these patients died. In 7 of the Type I. cases serum treatment was attempted, but 6 patients came under treatment too late for hopes of success to be seriously entertained, and died shortly after it was commenced. The seventh survived for eighteen days after a diagnosis of meningitis had been made, and showed at one period striking clinical improvement. The post-mortem appearances were, at the same time, remarkable enough to encourage the belief that cure is a probability if treatment can be undertaken energetically in the early stages of the disease. At least one case of recovery after the use of serum has been reported.[1]

The patient, a male metal-polisher aged 31, was taken suddenly ill on Jan. 20th, 1935, with pleural pain and rigors. Received at hospital at 11 P.M. on Jan. 22nd, he had the typical symptoms and signs of a right upper lobe pneumonia. A mouse was inoculated with sputum the same night, and 60,000 units of serum were given intravenously the following morning (23rd), and 30,000 on the 24th. Blood cultures taken on the 22nd, 23rd, and 24th were all sterile, but the general condition was poor, and cyanosis was present in spite of intranasal oxygen.

On the 25th headache, present in mild form at the onset, became severe, and the spinal fluid was found to be turbid, containing 8000 cells, chiefly polymorphs, per c.mm., and Type I. pneumococcus. 60,000 units of serum were given intrathecally on that day, 60,000 on the 26th, 50,000 on the 27th, and 40,000 on the 28th. Spinal puncture was performed each day thereafter, but no further serum given, until Feb. 2nd, when only 5 c.cm. of fluid could be obtained with difficulty. A cisternal puncture was made on Feb. 2nd and 40,000 units serum

introduced; on the 4th this was repeated, and 60,000 units given. On the 5th cisternal puncture was done, but no serum given. Lumbar puncture was always attempted before cisternal puncture was resorted to.

The nature of the fluid obtained, dosage of serum, and condition of the patient are shown in the accompanying Table.

Spasm of neck muscles and of hamstrings was present throughout, but diminished after Feb. 1st. Headache and mental confusion disappeared on Feb. 6th, but were replaced for 24 hours by depression. From the 7th to 9th he was afebrile, rational, and symptomless, sat up and demanded food. On the 9th there was some headache, which became more severe, and a few drops of spinal fluid obtained on the 11th were turbid. Cisternal puncture was again performed and slightly turbid fluid obtained. 60,000 units of serum were introduced. The patient was in good condition at the end of the procedure (performed under general anæsthesia), but collapsed half an hour later and died in five minutes. At no time was blood observed in the fluid obtained by puncture.

At the autopsy, in striking contrast to the usual appearances of the brain in pneumococcal meningitis, the meninges appeared entirely clean except for a small area, half an inch across, on the extreme vertex, where a small collection of more or less inspissated pus was found. Around the medulla, and filling the foramen magnum, was recent blood clot, the obvious cause of death. There was no hydrocephalus and the lung showed complete resolution. No suppuration was present in the middle ears or mastoid cells.

In this case it seems certain that hæmorrhage was caused by trauma during the introduction of the serum, although one was unaware of any movement of the needle, and this danger must be reckoned as a very serious disadvantage in treatment. On the other hand, it is probable that in every case of pneumococcal meningitis the giving of serum by lumbar puncture will become impossible before adequate treatment has been given, and cisternal puncture become the only means of continuing it. Recovery in one case of Group IV. pneumococcal meningitis has been reported[2] after cisternal drainage by open operation, and this line of treatment, combined with serum in Type I. and II. cases (without which it is unlikely that recovery will take place), seems to give a very reasonable hope of cure. The danger of concealed hæmorrhage is thus removed, and a drainage-tube, which can be opened intermittently, provides an easy method of applying serum directly to the meninges.

SELF-PERFORMED ENTERECTOMY

By Theodose Ch. Astreos, M.D.
DISTRICT MEDICAL OFFICER, PAPHOS, CYPRUS

The following case is interesting because the method of suicide chosen was unusual and because uneventful recovery followed treatment of a condition seemingly hopeless.

A man, claiming to be 75 years old, was brought into the Paphos Hospital by the police, bleeding from a self-inflicted wound in the abdomen. Three pieces of small intestine wrapped in rags were produced, which had been cut out of the patient's abdomen by himself. He was a beggar, who had been living all his life under miserable conditions, and he often complained that his abdomen was full of bed bugs, which he felt creeping up and down inside his abdomen. He had often been heard threatening to commit suicide or "to cut open his abdomen to let the bugs out."

According to the statement of eye-witnesses, the patient, while sitting by the public highway stripped himself from the waist down, and, using an ordinary pocket knife, stabbed himself low in the abdomen and drew the knife upwards. His bowels protruded and, before any one could prevent him he cut out in quick succession three pieces of intestine, which he threw away. The police wrapped him in some dirty canvas bags, that had just been emptied of animal manure, and rushed him to hospital. The distance was two miles and he was seen about twenty minutes after the attempt.

The patient appeared to be about 65 years old, fully conscious and rational. He was euphoric and his features showed no signs of pain. The pulse was rapid but of fair quality. The abdominal wound looked like a surgical incision, extending from below the umbilicus downwards for about 4 in. in the midline. Two freshly cut ends of small intestine were protruding through it. The mesentery was bleeding profusely, and the wound was smeared with faeces and dust of animal manure.

Two intestinal clamps were placed on the cut ends of the intestine and the bleeding from the mesentery controlled with 18 hæmostatic forceps, which were temporarily left in place. The wound was then covered with hot wet towels and preparations were hastily made for an operation. But the control of bleeding took some time, and before it was completed the patient collapsed. The pulse became threadlike. A subcutaneous injection of normal saline solution was immediately started and 800 c.cm. were given in about thirty minutes. By this time the pulse had improved sufficiently to permit operation under local anæsthesia. Novocain 2 per cent. solution with adrenaline was used while the patient was still collapsed. The ends of the intestine were pulled further out and a lateral entero-anastomosis was performed having cut off from both ends of the intestine about 3/4 in. The anastomosis was then covered with a fold of the omentum and this was fixed to the mesentery with three plain catgut stitches. The wound was once more cleansed with normal saline solution and ether, the incision renewed and lengthened by one inch, the contents replaced into the peritoneal cavity and the abdominal walls closed without drainage.

The three pieces of intestine, cut from one loop, measured 13, 14, and 17 cm. respectively, a total length of 44 cm. The protruded viscera were held in place tightly by the edges of the abdominal wound and this was one of the reasons that justified omission of drainage, the other being the fear that the patient might try to interfere with the wound in a second suicidal attempt.

Because of the patient's state of collapse it was thought that the avoidance of general anæsthesia would not seriously handicap the operation and that it would have the advantage of not permitting the abdominal muscles to relax and the viscera return into the abdominal cavity, increasing the danger of spreading the infection. There was also a slight chance that the rest of the abdominal cavity and contents were not infected.

Subsequent events justified this procedure, for the patient had an uneventful recovery and left the hospital on the fifteenth day, completely recovered. The absence of any fever seems remarkable, and it is interesting to speculate how much resistance to infection this man had accumulated during his long and miserable life as a beggar. Although he expressed no regret for his act and justified it, stating that "he had now got rid of the bed bugs," he later obeyed orders faithfully, when told that disobedience might have disastrous results. He continued to have excellent health and was free from any abdominal symptom when I last saw him.

I have to thank my chief, Dr. Cyril C. H. Cuff, for permission to publish this case.

ORGANISM OF SPIROCHÆTAL JAUNDICE IN A RAT FROM A NORTH OF ENGLAND COAL-PIT

By H. A. Cookson, M.B., F.R.C.S., M.R.C.P. Edin., D.P.H.

HONORARY PATHOLOGIST TO SUNDERLAND ROYAL INFIRMARY

Gulland and Buchanan[1] noted the occurrence of spirochætal jaundice in miners working in wet mines in Scotland. It would appear right to report the finding of an infected rat in a wet seam in the North of England.

On May 28th of this year, the miners' secretary of a lodge in the North of England, was directed to bring a living rat to me. The reason for this action was that one of the lodge members who had worked in a particular seam of this pit, had had an attack of what was (from hearsay), apparently spirochætal jaundice, others formerly suffering in the same way. I cannot better than quote from the secretary.

> "The seam this person worked in is known as the 'X' seam. The average height is 18 in., very wet, and the water lies in pools. At the entrance to this drift, there is a sewage disposal works and a refuse tip. From time to time the rat inspector has visited this place, owing to it being over-run with rats, and laid poison to exterminate them. Nearly every one of the several cases of jaundice has occurred in the same area known as the 'Y' flat in the 'X' seam."

The rat was alive when I received it. It was killed and examined, when it seemed healthy. The bladder was half full, and I examined the urine by dark-ground illumination, and thought I saw one spirochæte. I therefore inoculated a guinea-pig, intra-peritoneally, this on May 28th, 1935. The animal remained well until Friday June 7th, and it died during the night, June 7th–8th; it was noted that there was conjunctivitis and that the animal was jaundiced. Post-mortem examination made on June 8th showed subcutaneous tissues deeply jaundiced, with typical hæmorrhages into the lungs, the so-called "butterfly mottling." Preparations from the liver stained by Fontana's method for spirochætes demonstrated their presence.

Thus the occurrence of cases of jaundice in a wet seam was associated with the finding of *Spirochæta icterohæmorrhagiæ* in a rat caught in the same place.

INHERITANCE OF PHENYLPYRUVIC AMENTIA (PHENYLKETONURIA)

By L. S. Penrose, M.D. Camb.

RESEARCH MEDICAL OFFICER, ROYAL EASTERN COUNTIES' INSTITUTION, COLCHESTER

In a recently published paper[1] I described two brothers who were both idiots and who excreted an abnormal substance in the urine. This abnormal constituent was considered to by phenylpyruvic acid, a ketonic substance previously identified by A. Fölling[2] in the urine of certain imbeciles. The disease appears to be inherited recessively. More than one member of a sibship can be affected; the parents and the normally intelligent sibs do not excrete phenylpyruvic acid. In human populations, if a Mendelian recessive character is rare, practically all individuals in whom it is manifested will have parents who are carriers, that is to say, parents who carry the gene but who do not exhibit the character. In such families a fraction, approaching one quarter, of the brothers and sisters of a person who shows a recessively determined abnormality will show the same abnormality. Furthermore, as Garrod[3] first pointed out in connexion with alkaptonuria, the parents in these families will not infrequently be found to be consanguineous. Phenylpyruvic amentia, more conveniently termed phenylketonuria, is a rare disease and, if it is due to a single recessive gene, these criteria must be satisfied.

The present communication deals with a pedigree which was originally published[4] in order to demonstrate the mode of action of a rare recessive gene in a consanguineous family. Four female aments (previously referred to as four idiots but more correctly described as three idiots and one imbecile) were distributed among the offspring of two interrelated first cousin marriages. It was argued that the defectives represented a rare special type of amentia, hitherto undescribed, and due to a single recessive gene. This conclusion was based upon three observations—namely, the sharp segregation of the affected from the unaffected members of the family, the correct degree of familial incidence of the disease among the sibs, and the effect of consanguineous parentage. The stimulus provided by the recent work of Fölling has resulted in the discovery that the only survivor (generation IV., No. 4, on the attached pedigree Chart) of the four aments in this pedigree is a case of phenylketonuria. It is not unreasonable to suppose that the three aments in this family who have died suffered from the same disease. Dr. J. H. Quastel (who suggested the name phenylketonuria) and Dr. H. A. Krebs have kindly examined the urine of the surviving patient. Phenylpyruvic acid has been identified with certainty and several new problems have been raised which are still under investigation. If the assumption is correct that the three aments who did not survive (III. 3, III. 6, and IV. 7) suffered from phenylketonuria, there can be little doubt that the disease is the expression of a single recessive gene. Since the original publication of the pedigree which is under discussion some further details have been obtained. The Chart has accordingly been revised and a full description of it is appended.

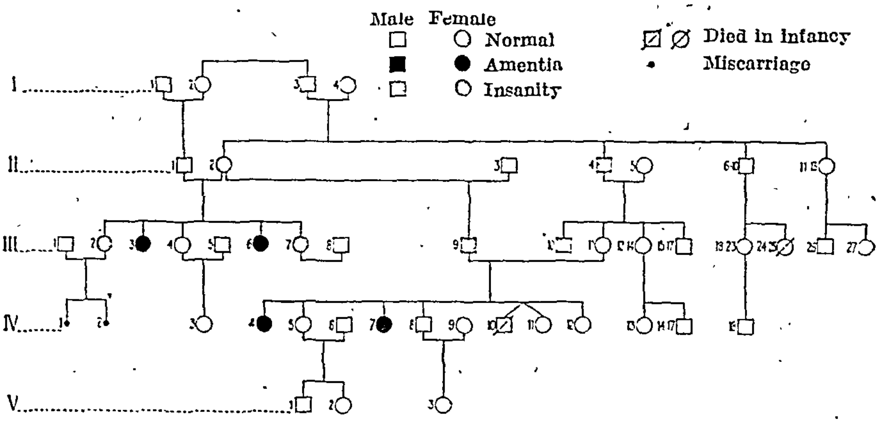
The genetical interest [illegible] this family does not cease with the recognition of the relationship between parental consanguinity and the appearance of a rare recessive [illegible] in the offspring. [illegible] recorded the [illegible] of mental disease in relatives of two of his patients. In the instances previously reported by me, the father began to suffer from

A PEDIGREE OF PHENYLKETONURIA



GENERATION I

1. Male; husband of I. 2; said to have been healthy; no further information obtainable.
2. Female; great great aunt of IV. 4; said to have been healthy; no further information obtainable.
3. Male; great grandfather of IV. 4; said to have been healthy; no further information obtainable.
4. Female; great grandmother of IV. 4; said to have been healthy; no further information obtainable.

GENERATION II

1. Male; husband of II. 2; healthy; died aged 81.
2. Female; paternal grandmother of IV. 4; showed signs of insanity when aged 75; died aged 77.
3. Male; no information obtainable.
4. Male; maternal grandfather of IV. 4; farm labourer; chronic melancholia from the age of 50; died aged 83.
5. Female; maternal grandmother of IV. 4; normal, so far as could be ascertained.

6–10. Males; normal, so far as could be ascertained.

11–13. Females; normal, so far as could be ascertained.

GENERATION III

1. Male; husband of III. 2; said to have been in a mental hospital; no details known.
2. Female; aged 59 now; recurrent mania with hallucinations; attacks at ages 23, 53, and 54.
3. Female; idiot—quite helpless; died at age of 4 years.
4. Female; died of peritonitis at about the age of 45; normal mentally.
5. Male; husband of III. 4; no information.
6. Female; idiot; never sat up—quite helpless; died at age of 4 years.
7. Female; suicide at age of 54 during an attack of melancholia.
8. Male; husband of III. 7; no information.
9. Male; father of IV. 4; illegitimate child of II. 2 and II. 3; b. 1866; aged 69 now; farm labourer; had a nervous breakdown at age of 44; has since been unable to work; now suffering from melancholia and chronic nephritis; urine contains no phenylpyruvic acid.
10. Male; b. 1864; farm labourer; melancholia with hallucinations; onset at 51; suicidal; died aged 54.
11. Female; mother of IV. 4; b. 1869; aged 66 now; healthy and mentally normal; urine contains no phenylpyruvic acid.

12–14. Females; normal, so far as could be ascertained.

15–17. Males; normal, so far as could be ascertained.

18–23. Females; normal, so far as could be ascertained.

24, 25. Females; died in infancy.

26, 27. Male and female; normal, so far as could be ascertained.

GENERATION IV

1, 2. Miscarriages.

3. Female; normal; accidental death at age of 14.
4. Female; b. 1894; aged 41 now; imbecile; mental age, judged by Stanford-Binet tests, 4 years 3 months, and by Porteus maze test, 3 years. She is excitable and talkative, stumbles over her words, and uses them in the wrong sense; she can run about, feed herself, and keep herself clean with supervision. Physically she is healthy, has a good appetite, but suffers from excessive sweating. She is small in stature, rather fat, has a mild degree of kyphosis, and is elderly in appearance; she has freckles on her face and hands with several small pigmented nævi on the limbs and neck; the head is small (cranial capacity, 1079 c.cm.; cephalic index, 0·79). The teeth are regular though the enamel is poor and the gums septic. The breasts are fairly well developed and menstruation has until recently been regular. The pupils react to light rather slowly and the ocular fundi are normal; slight coronary cataracts were observed by Dr. A. V. Taylor on examination with a slit lamp. The patient was neurologically investigated by Dr. S. Nevin, who reported that, although all tendon reflexes were exceptionally brisk, there was no definite sign of a pyramidal lesion. The urine contains phenylpyruvic acid.
5. Female; sister of IV. 4; b. 1897; aged 38 now; normal.
6. Male; husband of IV. 5; normal.
7. Female; sister of IV. 4; b. 1900; idiot; never learned to talk but could say one or two words which she used for anything and everything; no fits; unable to walk but showed no definite signs of paralysis; unable to attend to herself; died aged 15.
8. Male; brother of IV. 4; born 1903; aged 32 now; railway clerk.
9. Female; wife of IV. 8; normal.

10. } Twins; sibs of IV.4; b. 1906 { (i) Male; died in convulsions aged 14 days.
11. }   { (ii) Female; aged 29 now; in domestic service; normal intelligence; phenylpyruvic acid absent from urine.

12. Female; sister of IV. 4; b. 1909; aged 26 now; works for a newsagent; normal intelligence; no phenylpyruvic acid in urine.
13. Female; normal.   14–17. Males; normal.   18. Male; b. 1930; normal.

GENERATION V

1. Male; b. 1924; normal.   2. Female; b. 1930; normal.   3. Female; b. 1926; normal.

delusions during the involutional period and the paternal grandfather showed similar signs during senility. The pedigree dealt with in the present communication contains six relatives who showed definite signs of insanity, of which the mean age of onset was about 50 years. Three of these individuals (II. 2, II. 4, and III. 9) were certainly carriers of the gene which produced idiocy in their homozygous offspring. For two of the remaining three (III. 2 and III. 7) the chances in favour of their being carriers are two to one and the chances that III. 10 is a carrier are even. The hypothesis may be advanced that the gene for phenylketonuria is not completely recessive, but that it exerts an influence upon the heterozygotes—the carriers—which predisposes them to mental breakdown. Although the homozygous individuals—the aments—are rarities in the general population, the carriers are much less infrequent and it is possible that a significant proportion of mentally disordered persons may belong to this class.

SUMMARY

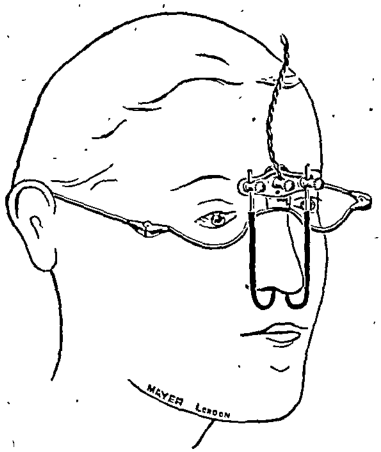
The pedigree of a case of phenylpyruvic amentia (phenylketonuria) has been recorded which demonstrates the mode of inheritance of this condition. A single recessive gene is held to be the cause. Not only does this gene cause amentia when present in the individual in homozygous form, but the heterozygotes or carriers show a marked tendency to develop insanity in the involutional period of life.

The investigation was carried out under the auspices of the Medical Research Council and the Darwin Trust. I am much indebted to Miss D. E. Newlyn for obtaining details of the family.

NEW INVENTIONS

APPARATUS FOR NASAL IONISATION

The apparatus shown in the figure is a modification of that of Mr. Philip Franklin. It consists of a spectacle frame into which fit two nasal electrodes. The advantages claimed for this apparatus are as follows :—



1. It does away with the band which in Franklin's apparatus fixes the electrodes to the patient's head and keeps it in this position for about twenty minutes. My patients used to complain greatly of the inconvenience and discomfort caused by the band, both during and for several hours after the treatment.

2. The frame is applied like ordinary spectacles by the patient himself. It rests on the bridge of the nose, the terminals of the frame, therefore, being always in the same line as the nostrils. This makes the fixing of the nasal electrodes of the frame, after their introduction into the nose, a very precise and easy procedure, and one which causes the patient the least possible discomfort.

Mayer and Phelps, of New Cavendish-street, W.1, have made this apparatus for me.

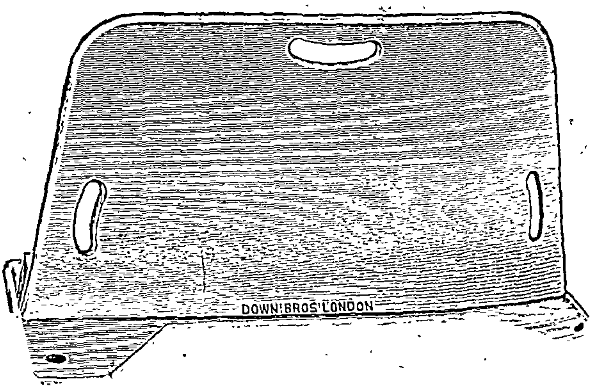
London, W. Arthur Miller, F.R.C.S.Edin.

FRIPP-McCONNEL BED-CLOTHES SUPPORT AND EXERCISER

This apparatus has been designed to serve two purposes: (*a*) To keep the weight of the bed-clothes off the patient's feet, and by supporting the soles of the feet, to prevent him getting foot-drop. (*b*) To help him to exercise certain muscles, while lying in bed, so as to shorten his convalescence when he is up.

The illustration shows the side which should be placed against the patient's feet when it is used as a bed-clothes support. It can be tethered to the bed in such a position that the feet rest comfortably against the vertical board, and so the tendency to foot-drop is guarded against. On the other side there is a bar to support the heels and two diagonally placed battens for the pads of the four outer toes. This side should not be used for too long at a time; otherwise a pressure sore may appear on the heels.

The object of using the support in this way is to prevent deterioration of the muscles while the patient is in bed, and to enable him to regain a good balance and posture when he gets about again. He can thus exercise the following muscles: (*a*) The short muscles of the foot and the tibialis group. (*b*) The quadriceps and gluteal muscles, by pressing his knee downwards against the mattress, with the sole of his foot supported. (*c*) The oblique and transverse muscles of the abdomen which are automatically brought into action by this exercise. A piece of bandage should be tied to the exerciser so that the patient can draw the latter towards him in bed to suit his position.



The support and exerciser can be used with advantage in any case where a patient is confined to bed; but it is particularly useful in long debilitating illnesses when the leg muscles and the sense of balance tend to deteriorate.

Messrs. Down Bros., 21, St. Thomas's-street, S.E., are the makers of the apparatus.

A. T. Fripp, F.R.C.S.Eng.

Norfolk and Norwich Hospital.—This hospital has a deficit of over £10,000, but owing to the success of the contributory scheme the board has decided to push ahead with the erection of new balconies, and it will probably have to enlarge the X ray department.

MEDICAL SOCIETIES

BRITISH ASSOCIATION OF RADIOLOGISTS

THE first annual general meeting and Congress of this association was held on July 12th and 13th, in the University buildings, Birmingham, and was attended by a large and representative gathering of radiologists.

Dr. JAMES F. BRAILSFORD (Birmingham), in his presidential address, traced the progress of radiology through its pre-war, war, and post-war phases, and paid tribute to the early workers in radiology, many of whom had sacrificed their lives to its development. He outlined the objects of the Association and pointed out that in addition to the annual congress at which radiologists from all over the country may interchange views, the Association will provide a medium of coöperation by which the advancement of radiology may be promoted in its ethical, educational and economic aspects. Dr. Brailsford announced that a Fellowship of the Association had been founded, outlined the rules governing admission to this Fellowship, and said that 14 Founder Fellows had been elected, all of whom had already been honoured with high radiological office by their colleagues.

After the presidential address, on July 12th, a visit was paid to the new buildings at the Birmingham Hospital Centre now in process of erection at Bournbrook, where the plans of the new X ray department were inspected.

In the afternoon the association inspected, at the University buildings in Edmund-street, a representative exhibition of radiograms of bone and joint conditions which had been assembled by the president from his own collection and from those of many other members.

CLINICAL PAPERS

On July 13th Dr. R. E. ROBERTS (Liverpool) opened a discussion on Ante-natal Radiology and described his method of cephalometry as a means of estimating the maturity of the fœtus.—Dr. L. A. ROWDEN, of Leeds, gave an account of his method of pelvimetry. Dr. J. DUNCAN WHITE, Dr. C. L. McDONOGH, and Dr. G. VILVANDRÈ took part in the discussion which followed.

Dr. J. H. DOUGLAS WEBSTER introduced a discussion on Methods and results with pre- and post-operative radiation in Breast Cancer. He briefly outlined the development of the methods which had been used in a number of centres; and he quoted statistics of his own and of others from which it appeared that the percentage of five-year "cures" might be doubled after a suitable combined course of radiation and operation, as compared with operation results in similar groups of cases. Several recently introduced methods had given better results than the more primitive technique.

Dr. HARRISON ORTON, Dr. F. HERNAMAN-JOHNSON, Dr. G. VILVANDRÈ, Dr. J. E. A. LYNHAM, Dr. RALSTON PATERSON, Dr. W. BARRINGTON PROWSE, and Dr. W. GRIFFITHS contributed to the discussion which followed.

Dr. S. GILBERT SCOTT read a paper on Spondylitis adolescens, its clinical and radiological features and the results of X ray treatment.

REVIEWS AND NOTICES OF BOOKS

A History of Science, Technology, and Philosophy in the Sixteenth and Seventeenth Centuries

By A. WOLF, Professor and Senator, University of London; Head of the Department of History and Methods of Science. With the coöperation of Dr. F. DANNEMANN, Professor in the University of Bonn; and Mr. A. ARMITAGE, of University College, London. London: George Allen and Unwin Ltd. 1935. Pp. 692. 25*s*.

No reviewer will attempt to deal in any detailed manner with this book; its range is too large, while so many of the sections treat elaborately of technicalities that it would require a team of experts to evaluate, just as it has taken the help of a team of experts to produce them. Prof. Wolf attempts to give a full protrait of the mind of the sixteenth and seventeenth centuries, and one has only to think for a moment of those who were the intellectual leaders of the period, of what they attempted and to what they led their successors, to realise that huge as this volume is it can be but a curtailment of facts in many directions. For in those centuries the foundations of modern science and philosophy were laid. But we find in these pages summaries, and in some cases detailed accounts, of much which was most important in that early work, and which, where it was sound, proved to be largely the foundation on which the wisdom of to-day rests. Astronomy, biology and physics, chemistry, economics and statistics, geology and geography, are the obvious headings of the sections, medicine having a chapter to itself, and properly following on the section devoted to anatomy and physiology. And the way in which medicine is dealt with is an example of the treatment of the various subjects. With strict reference to the period under consideration nothing is said of the fathers of the science and art of medicine, and the earliest workers in anatomy and biology referred to are Vesalius, Servetus, Fabricius, Malpighi, Leeuwenhoek, and certain of their contemporaries. The story of Harvey's discovery finds its place under the heading of anatomy, and is told in the barest outline, but, as always, it is thrilling because of first the logical manner of approach, and, secondly, of the wonderful manner in which the inevitable gaps were later closed in accordance with the original theory. The medical protagonists chosen for mention are, among others, Fracastoro, Sanctorius (inventor of the weighing chair), Glisson, Paracelsus, a pioneer in chemistry, the value of whose work escapes general knowledge, Paré, Mayow, Gilbert, the author of *de Magnete*, Van Helmont, John Locke, and Borelli, while the comment affixed to the list, abbreviated here, is that the majority of the famous doctors enumerated were pioneers in other fields of study than pathology. That is a suggestive reflection to-day, when on all hands it is seen how dependent for any live progress scientific medicine is upon the research work of the biologist, the physicist, and the philosopher.

British Scientists of the Nineteenth Century

By J. G. CROWTHER. London: Kegan Paul, Trench, Trubner and Co. 1935. Pp. 332. 12*s* 6*d*.

THIS is a well-written and interesting little book containing the biographies of Humphry Davy, Michael Faraday, James Prescott Joule, William Thomson, and James Clerk Maxwell, with pictures of the heroes at different stages of their lives. What each of them did and what its value has been to succeeding generations is clearly explained in simple language.

Physical Diagnosis

Seventh edition. By WARREN P. ELMER, B.S., M.D., Associate Professor of Clinical Medicine, Washington University; and W. D. ROSE, M.D., late Associate Professor of Medicine in the University of Arkansas. London: Henry Kimpton. 1935. Pp. 919. 35*s*.

THIS volume is a modernised version by Dr. Elmer of a text-book originally published by Dr. Rose in 1917. The book is divided into two parts. The first 200 pages deal with surface anatomy and inspection of the various parts of the body; there follow chapters on palpation, percussion and auscultation, the reflexes, and special diagnostic procedures such as radiology and electrocardiography. The method of approach to clinical medicine here followed should result in a thorough grounding in systematic observation, though some students, who have ample opportunity of examining patients, will probably find a more compact volume on clinical methods more to their liking.

In Part II. the diseases of the respiratory and circulatory systems are discussed in a similar manner to that usually adopted in text-books of medicine. It is dificult to understand the author's reasons for concluding a book on physical diagnosis with some 300 pages dealing with diseases of the chest alone.

The Modern Treatment of Hæmorrhoids

Third edition, revised. By J. F. MONTAGUE, M.D., F.A.C.S., of the Rectal Clinic, University and Bellevue Hospital Medical College, New York, &c. London: J. B. Lippincott Co. 1934. Pp. 318. 21*s*.

IN its third edition Dr. Montague's well-known book on the treatment of hæmorrhoids shows little change. It gives sound instruction as regards pathology, ætiology, and examination procedures. Operation under local anæsthesia is recommended for the majority of cases, the method being either a catgut ligature operation, or a clamp and cautery. In selected cases of single, small internal piles injection is recommended: the author adheres to his previous technique and recommends injection into the pile mass of 10 per cent. cresylic acid in glycerin and water, or 10 per cent. carbolic acid in olive oil. The submucous injection above the pile of the popular 5 per cent. phenol in oil is not described. Dr. Montague retains a chapter on the treatment of internal piles by insertion of radon seeds, but seeing that he has to admit unsatisfactory results in 12 out of 35 cases there does not seem to be much merit in this treatment: nor does there seem to be adequate reason for re-describing certain electrical methods which the author himself does not find particularly convenient or efficient. Chapter XVIII. on the recurrence of hæmorrhoids is unchanged from the previous edition: the author states that the recurrence-rate is greater after injection than after operation but no definite evidence of this is provided. In a new chapter Dr. Montague speaks with enthusiasm of the adoption of rectal avertin anæsthesia: he has now used it for 578 rectal cases, and although he admits that it does not give as good relaxation of muscles as the inhalation methods it has given sufficient anæsthesia for the usual routine operations, being supplemented sometimes with local anæsthesia. No deaths in his cases have been attributed to the use of avertin.

The book will be of interest and value to many physicians and surgeons, particularly to those who have the experience which will enable them to discriminate between the methods offered. A good deal of obsolete matter could with advantage have been deleted. In particular the columns on differential diagnosis (Ch. VIII.) may prove a stumbling block to the ignorant and trustful: thus in a table on p. 94 we are told that carcinoma of the rectum occurs in patients usually over 40 years of age, bleeding being slight and a barium enema showing an obstructive lesion of the bowel. Unfortunately the variants from this neatly outlined composite picture are so numerous that the table is frankly useless.

Die Krebsbehandlung in der täglichen Praxis

By Dr. ALFRED NEUMANN. Leipzig: Weidmann and Co. 1935. Pp. 354. RM.18.

THIS book is an easily written undiscriminating collection of information about cancer. The general symptomatology is briefly considered, as are the diagnostic points when the disease manifests itself in certain sites. A large number of methods of treatment, general and special, are set out with illustrative cases. The book, we learn from the publishers, has been specially written with a view to being of service both to the research worker and the practitioner, and as a voucher for its standing many columns of names of authorities, mostly German, are quoted. Those of our readers to whom the language presents no difficulty will find here a serviceable compendium.

Illustrative Electrocardiography

By the late JOSEPH H. BAINTON, M.D., formerly Attending Physician and Chief of the Cardiac Clinic, Morrisania City Hospital, New York, and Consulting Physician, St. John's Long Island Hospital; and JULIUS BURSTEIN, M.D., Associate Electrocardiographer, Morrisania City Hospital, and Cardiologist to St. Elizabeth Hospital, New York City. London: D. Appleton-Century Company. 1935. Pp. 258. 21*s*.

THIS is an atlas of electrocardiograms intended for the student and the non-specialist. It contains 155 records, made with a string galvanometer instrument and a continuous film camera, and reduced to about two-thirds of their original size. The reproduction is clear, but it would have been more satisfactory to give full size electrocardiograms of shorter length. The accompanying text is simply a description of the records, beginning with a chapter on the fundamental waves and their time relationships, and proceeding through the varieties of normal curve and most of the recognised abnormalities. The latter are interpreted in accordance with accepted canons. Artefacts and multiple abnormalities are illustrated at the end. The book should fulfil its modest purpose well, and may be recommended to students who have no access to the collected records of a reliable electrocardiographic department.

THE LANCET

LONDON: SATURDAY, JULY 27, 1935

THE REPORT ON THE OSTEOPATHS BILL

ON another page will be found the report of the Select Committee of the House of Lords on the Osteopaths Bill. It should be noted that the report is unanimous, with no reservations, and this is in itself an achievement little short of astonishing when one considers the differing standpoints from which the members of the committee approached their task. They agree that it emerged clearly from the evidence submitted that osteopathy is not, as is popularly supposed, a craft or art limited to the treatment of maladies or defects of the bones, joints, muscles, and ligaments, by manipulation. In this sphere they have no doubt that qualified osteopaths perform valuable services, and, though they do not say so, it is pertinent to add that bonesetters, with no claims to any special form of qualification, may perform services no less valuable. (Incidentally the committee state that they have not been in any considerable degree influenced by evidence either of cures or of failures, since all methods of healing can provide examples of either.) Osteopathy, however, claims to be a method of healing which is suitable to the treatment of diseases of any description. In spite of the proposed insertion of clauses excluding osteopathy from the practice of "major surgery," midwifery, and anæsthetics, the principal witnesses supporting the Bill, when asked whether they would be willing to delimit the sphere of activities of osteopaths, made it abundantly clear that a claim to treat all diseases is made. It is in fact an alternative system of medicine for which statutory recognition was asked, a system for which there is no scheme of organised education in this country other than an establishment which was characterised in the report of the committee as "of negligible importance, inefficient for its purpose, and above all in thoroughly dishonest hands." The committee reached the conclusion that the claim of the osteopaths to be able to treat all diseases has not been established, and that it would not be safe or proper for Parliament to recognise osteopathic practitioners as qualified, on a similar footing to that of registered practitioners, to diagnose and treat all human complaints. They hold that the question of establishing a register of osteopathy by Act of Parliament should in any case be deferred until the sphere of osteopathy has been defined and a system of education in its principles and practice has been developed in this country in one or more well-equipped and properly conducted institutions.

The answer to the question raised in the course of the hearing as to whether there should be what was described as a "scientific inquiry into the merits and practice of osteopathy" is answered by implication in the reiterated conclusion that "the claim of the osteopaths to be able to treat all diseases has not been established." The recommendation that the Bill be not further proceeded with carries therefore finality which will, it may be hoped, be interpreted as precluding the necessity of expending public money on any further inquiry.

THE DETECTION OF DEFECTS IN SCHOOL-CHILDREN

IN the city of New York there are 635 elementary school buildings with about 760,000 children. For every 100,000 children there are approximately 2700 teachers, 40 school nurses, the equivalent of 7 whole-time medical officers, 2 dentists, and 3 dental hygienists. With the aid of a liberal grant from the Metropolitan Life Insurance Company and the coöperation of the city departments of education and health, the American Child Health Association has attempted to ascertain whether the best use is being made of this personnel to detect seriously diseased or defective children and to ensure that their defects are remedied.[1] The investigation was conducted over about 18 months, commencing in January, 1932—i.e., during the period of depression. Attention was concentrated on children about the middle of school life, and on a limited group of defects, viz., defective vision, dental decay, defective hearing, subnormal nutrition, enlarged tonsils, and pediculosis. "Health awareness," a measure of the effect of education in hygiene, was also tested.

The methods of investigation, the results and the conclusions reached, are set out in a report now issued; the methods resemble those which have been described in previous publications of the Association and in the writings of Dr. RAYMOND FRANZEN. Large groups of children in fair samples of the city's schools were examined for each type of defect by a selected team. The history of the seriously defective was then traced in relation to their contact with the health organisation and an attempt was made to trace the link in the chain where a breakdown, if any, had taken place—whether the teacher or the nurse had failed to detect abnormality, or the physician had misdiagnosed at routine inspection, or there had been failure to follow up, or inadequate explanation to the parent or neglect or incapability on the latter's part. A fairly large error of detection was found, especially on the side of deficiency as regards malnutrition and excess in tonsillar disease; a lack of standards caused the trivial defects to receive attention to the detriment of the more severe ones; there was an overburdening of the follow-up staff and inadequate understanding between the elements of the machine. Without increasing the annual budget, the whole organisation could clearly be made much more efficient. Dr. FRANZEN and his co-workers believe that their findings would probably be repeated if similar inquiries were made into the working of the service in many other towns; and they make constructive recommendations under each heading.

---

[1] Physical Defects: the Pathway to Correction. American Child Health Association, New York, U.S.A. 1934. Pp. 171.

While the British system, with its whole-time officers working in small teams, is probably less prone to some of the errors recorded in this report, there are probably few areas where deficiencies of a like nature would not be found. The method of inquiry, described here in detail, might well be applied internally by chief school medical officers from time to time as a means of detecting flaws in their machine. In particular the mode of approaching the assessment of nutrition, by screening out the suspects with the help of the A.C.H. index, deserves wider trial in this country than it has so far received. This index, consisting of the ratio of the width of the hips to the difference between arm girth and chest depth, has been fully described by Dr. Franzen.[2] Probably few will agree that the selection of children for dental examination can be left to teachers and nurses, as the writers appear to contemplate. This is a branch of school medical work which must be specialised from the beginning at any cost. The report will repay study by all who are doing school medical work, the more so since the value of this service is being widely questioned even among those who are devoting their lives to it.

POST-MORTEM TECHNIQUE AND INTERPRETATION

Over a century has passed since it was first recognised that many physical signs and symptoms are dictated and can be explained by anatomical changes in organs. This fact plays an important part in the training of the student and is constantly being confirmed by the experience of clinicians who habitually visit the post-mortem room. It is a matter of history that it was the combination of careful study of patients in hospital with that of morbid anatomy that formed the basis of the achievements of such men as Hunter, Laennec, Bright, Addison, and Hodgkin, to name only a few. However, during the successive periods when bacteriology and biochemistry were first assuming clinical importance it became the fashion to contrast the so-called "pathology of the living" with the pathology of the dead, with some show of satisfaction that this last was obsolescent. The pendulum is swinging back with the advance as a scientific method of experimental pathology, for it is on the interpretation of the lesions obtained and their comparison with those produced by natural disease that much of the value of this method depends. The revival of interest in morbid anatomy has also been stimulated by the greater precision which has been brought to the diagnosis of structural abnormalities of the internal organs by X rays. This especially applies to the thoracic cavity, where the indications for and end-results of modern surgery and radiotherapy have not yet been fully explored. If there is a difference between the modern attitude to material removed at operation or from the dead subject and that of the morbid anatomists of the past, it is that the outlook now is dynamic rather than static, and it is always as a stage in a process of disease or repair that any abnormality is considered.

As Dr. W. G. Barnard well says in a pamphlet recently published[1] on the technique of a post-mortem examination, the object of such an examination should be to analyse the changes in each individual organ so as to arrive at a coherent account of the processes which have been active in the body. To enable the worker to do this an orthodox technique has become almost universal. The method advised by Barnard as "a guide to keen clinicians who themselves undertake post-mortem examinations," and written from the central histological laboratory of the L.C.C. at Archway Hospital, differs but little from that described by Dr. D. R. Coman[2] as practised in the pathological institute of McGill University; both are based on the classical work of Virchow. There is of course inevitably some variation in practice, as every skilled worker will have his own methods of choice. For instance, Coman gives the removal of the thoracic organs in toto only as an alternative technique, whereas it is the routine most usually practised in the London teaching hospitals. Such variations have little disadvantage provided the dictum of Orth is remembered: "the chief requisite of every exact post-mortem examination is that no part shall be displaced from its position until its surrounding parts are established, and that no part shall be taken out by the removal of which the further examination of other parts is affected." Barnard heads his description by the wise warning "The most important rule of all is: Look before you cut and do not cut unless you can see what you are doing." For workers less skilled it might be well to add—do not cut unless you know *what* you are cutting. Barnard's description is short, concise, and adequate and deals only with technique, a brief paragraph being given on examinations for coroners. It seems curious that all reference to special precautions in cases of accident, suicide, or suspected poison should be omitted in Coman's much bigger handbook. In other respects this book gives all essential details, and with the clear diagrams supplied should enable any practitioner of average knowledge to go through the motions of a thorough post-mortem without disgrace.

There remains, however, the question whether he can interpret the material displayed. There is in many quarters a view that this is mostly a simple matter—a view that is not shared by experienced pathologists. The East Ham insurance committee recently circularised all such committees in England and Wales on the subject of the arrangements made by coroners for post-mortem examinations. Apparently it is now the policy of the coroner for that area to employ one particular pathologist for all these examinations, whereas in the past, apart from exceptional criminal cases, it was customary to call on the general practitioner attending the case either to perform the examination or at least to be present thereat. The committee concerned expressed the pessimistic view that the post-mortem room is the one place where doctors learn the truth, and that attendance at post mortems provides "valuable opportunities for general practitioners to further their experience of pathology and, in the case of their own patients, often affords them facilities for corroboration in the very real problem of diagnosis." The response to the circular shows that in the main insurance committees are disinclined to accept the suggestion that in normal cases the patient's medical attendant, or the practitioner called to the case, should be selected to perform the post-mortem examination, and that in cases deemed to require the services of an expert pathologist the general practitioner should be invited to be present. Of the panel committees some have decided to support the proposal, while others agree that the practitioner should have the opportunity to attend every such examination while not subscribing to the view that he should necessarily be called upon to perform it. In reply to a question in the House on this matter the Home Secretary pointed out recently that since the passing of the Coroners (Amendment) Act, 1926, it has been open to a coroner to request any legally qualified medical practitioner to make a post-mortem examination and that he has no power to interfere with this discretion.

---

[2] Amer. Jour. of Dis. Child., 1934, xlvii., 789.

[1] Technique of a Post-mortem Examination. By W. G. Barnard, M.R.C.P., M.R.C.S. London County Council. 1935. No. 3121. Pp. 7. 2*d*.

[2] Technique of Post-mortem Examination. Compiled by D. R. Coman, M.D., C.M. Montreal: Renouf Publishing Company. Pp. 47. 6*s*. 6*d*.

In a memorandum of evidence to the Departmental Committee on Coroners' Law and Practice now sitting, the British Medical Association notes [3] that coroners are increasingly availing themselves of the provisions of Section 22 of the 1926 Act, under which they can call in specially qualified persons to make post-mortem or other examinations, and the Association makes no suggestion for restricting their freedom of choice in this respect. But it feels that the position of the practitioner who was in attendance prior to death is not fully safeguarded by existing provisions and proposes that (*a*) if he has not been asked to perform a post-mortem he should be given an opportunity of being present, no fee being paid for such attendance; and (*b*) the coroner should have discretionary power to invite the practitioner to be present if he has not been asked to perform the post-mortem and that the statutory fee of one guinea should be paid in such cases. We have every sympathy with the desire of the practitioner to follow his fatal cases to the post-mortem room, but at the same time it is clearly desirable that autopsy should be performed by people who are specially qualified by training and experience for this work. A compromise on the lines suggested by the B.M.A. appears to meet the situation. The educational value of a post-mortem to which the East Ham insurance committee draws attention will be far greater to the practitioner who watches it performed and demonstrated by a pathologist than to one who attempts unaided to solve problems whose wider significance can only be recognised by an expert.

THE PHYSIQUE OF MAN IN INDUSTRY

THE golden age is always in the past and we can read, almost daily, that the present generation is inferior to its predecessors either physically, mentally or morally—or, indeed, in every way. But the sceptic can remain unmoved by this indictment, and point with justice to the absence of well-founded standards by which we can measure the deterioration alleged. General impressions are apt on occasions to be surprisingly misleading, and with regard to physique the desideratum must be a large and representative body of anthropometric data. The lack of such material in this country was pointed out many years ago by the Interdepartmental Committee appointed after the Boer war to inquire into physical deterioration. They could find no satisfactory evidence to support the belief in a general progressive deterioration, but they carefully underlined the fact that no sufficient material was available for a comparison of the physique of the nation with its status in the past. So far as an anthropometric survey was concerned, however, their report led to no action. Interest was once more widely awakened with the publication of the famous "C 3" report, but as this related to men examined in the last year of the late war, it was rightly held that such a sample could not possibly be taken as representative of the manhood of the country.

This absence of representative data forms one of the reasons which has led the Industrial Health Research Board to initiate a wide and careful investigation into the physique of men in industry, a report upon which has now been issued.[1] The work has been directed by Prof. E. P. CATHCART, F.R.S., and all the measurements were made by two workers, Mr. D. E. R. HUGHES and Mr. J. G. CHALMERS. Between them they have recorded the height, weight, strength of grip, strength of lift or pull, and distance of middle finger tip from the ground of 13,656 individuals—10,593 employed men, 1328 unemployed, and 1735 university undergraduates, drawn from nearly all parts of the country and industries. The very detailed statistical analysis to which this material has been subjected reveals some curious results. For instance, the maximum height seems to be reached at about 20–21 years of age, and after about the age of 25 there is a gradual and fairly steady decline. Is this due, as the report suggests, to the development of a less erect carriage with advancing years, or to an absence of a proportion of the most physically fit at higher ages due to casualties in the war; or is it evidence of greater height in young adults such as has certainly been demonstrated in school children? The unemployed men were found, on the whole, to be a little inferior in weight, and in the tests of strength definitely inferior to their employed brethren. These men had been continuously unemployed for six months and more, and the question arises whether their reduction in strength is a consequence of their enforced idleness or whether they represent the unemployable—the last to be employed when work is abundant, and the first to be discharged when work is scarce. The authors of the report conclude that the sample measured by them is drawn from the latter class and is, therefore, unrepresentative of all the unemployed.

---

[3] Brit. Med. Jour., Supp., June 22nd, 1935, p. 282.

[1] Industrial Health Research Board. Report No. 71: "The Physique of Man in Industry." London: H.M. Stationery Office. 1935. Pp. 42. 1s. 3*d.*

The most striking characteristic of the measurements when divided into occupational groups is the uniform superiority in height of the "black-coated" group. In tests of strength, on the other hand, they did not excel and their strength of pull was definitely inferior to that of men in manual occupations. Geographically, London men are in their average height and weight definitely above the employed group as a whole—perhaps the result of selective migration of the more physically fit from the country districts. In spite of their extent, the data are not sufficient to determine how far heavy industries attract men of superior physique, or to what extent mechanisation has equalised the demand for brawn and muscle, and no satisfactory index of physical fitness has been evolved from them. But these sample figures are likely to prove the first approximation to the standard we need to determine whether the physique of entries to industry is being maintained, improved, or is deteriorating. In their collection Prof. CATHCART and his associates seem to have been granted willing assistance by the employers approached, and it is satisfactory to note (as evidence opposed to national deterioration mentally) that they are spared the explanation of failures given by Dr. BEDDOES, engaged on the same quest in 1870—namely "in Scotland to greed of time or to superstition; in Ireland to carelessness or to political feeling; in Wales to suspiciousness; and in England to stupidity"!

ANNOTATIONS

MILK PROCESSING AND CONTROL

IF civilisation may be defined as the conscious pursuit of quality, the City and Guilds of London Institute, in collaboration with representatives of the dairy industry and assisted by a strong advisory committee, have taken a notably civilised step in devising and issuing syllabuses for examinations in "Milk Processing and Control."[1] There can be no doubt that if their action is adequately supported by the dairy industry, there will be in course of time a steady increase in the competence and number of technical men now urgently needed for the effective operation and control of processing and manufacturing plant in all branches of the milk industry, and an accompanying improvement in the general standard of quality of our processed milk and manufactured milk products.

The syllabus and regulations embrace two examinations (i) one of "intermediate" grade for which a preparation period of five hours per week in a technical institution during the winter sessions of each of two years—i.e., some 200 hours altogether of lectures and practical instruction—is suggested as reasonable, and for which the syllabus includes some elementary chemistry, elementary physics and simple microbiology, and (ii) a final examination, open to those who have passed the intermediate examination, in (*a*) milk processing and milk products manufacture (pasteurisation, sterilisation, ice cream, condensed and dried milk products) and/or (*b*) the chemical and bacteriological control of milk and milk products, in the latter case clearly intended for those who are to work in fairly responsible technical positions in dairy industrial laboratories, or in laboratories outside the industry dealing with the control of milk and milk products. For the final examination, either (*a*) or (*b*), a period of study covering a further period of two years is suggested as advisable. The British Dairy Farmers' Association, in conjunction with the University of Reading, have had satisfactory courses of instruction in dairy running for some time, but the processing and manufacturing industry has been without similar provision for technical education. It is clearly to the advantage of all concerned—to the milk producer, to the distributor or manufacturer, to the consumer, and to the individual himself—that any person who is in charge, say, of a pasteurisation plant or an ice-cream plant shall have had at some time a reasonable training in the elements of science as applied to what is, nowadays, a highly technical job. The costly and complex plant used to-day, requires and demands knowledge and technical ability in increasing measure as its capacity and complication increases, and these are required not only for the laboratory control of the product at every stage but for the proper running and economical maintenance of the plant itself. In pasteurisation, for example, a process of first importance from the public health standpoint, it is impossible not to realise that, with some outstanding exceptions, the level of technical knowledge and ability displayed by the men in technical charge of the plant has little relationship to the high quality of the plant itself or to the amount of capital invested in it. As a result, the word "pasteurised" on the bottle of milk in the consumer's hands is in too many cases grossly misleading, as was clearly brought out in our columns recently by Prof. H. D. Kay, and Mr. F. K. Neave.[2]

THE ANATOMY OF THE HAND

STUDIES in the anatomy of the hand and its relation to infections have recently been undertaken by a group of workers in the University of Lille. Prof. Cordier, with the help of M. Coulouma, has made careful dissections of the hand, supplemented by injections of plaster, barium, and lipiodol, and subsequent radiography.[3] [4] He has come to the conclusion that in the upper part of the palm of the hand is to be found a compartment corresponding to each finger. The thenar space corresponds to the thumb, and its medial limit is more usually the second metacarpal than the third. Each digit is represented by a space, that of the index being well separated from the others. In the case of the other digits septa run forwards and backwards from the tendons, thus creating pre- and retro-tendinous compartments. The septum running back to the third metacarpal is especially constant. In the lower part of the palm have been found two channels; one for the lumbrical muscle and one for the tendons. In the case of the thumb the adductor carries a sheath and thus acts in much the same way as a lumbrical muscle. Thus each finger may communicate with its own palmar compartment, whilst the little finger communicates also with the hypothenar space and the thumb communicates with the thenar space and with the compartment for the index. The compartments for the index and middle fingers communicate with the thenar space via the branches of the median nerve. The practical application of this work is to emphasise once again the necessity for early operation in infections of the fingers tending to track towards the palm, so that the correct incision may be made before the pus has ruptured from one compartment into another. The incisions for opening up the lumbrical canal and the tendon sheath correspond with those recommended by A. B. Kanavel.[5]

SOME ASPECTS OF GLAUCOMA

THIS is the title of a lecture recently given by Mr. R. Affleck Greeves.[6] Many years ago Mr. Treacher Collins demonstrated structures in the ciliary body resembling glands, and suggested that they actually do secrete the fluid known as the aqueous humour. This theory has never been generally admitted, and of late years has gone very much out of favour. Mr. Greeves writes: "The points of similarity in structure between the ciliary processes and the choroid plexus of the brain are, in my opinion, strongly suggestive of a similarity in function, and therefore of a probable secretory element in the fluid production in the eye." Most modern authorities hold that the aqueous is not a secretion but a dialysate, and that the part played by its circulation and the integrity of its channels of egress in the pathology of glaucoma is comparatively slight. Mr. Greeves considers, on the other hand, that the time-honoured custom of laying the blame for abnormally raised tension on the non-functioning of these channels is fully justified. On the question of diagnosis his attitude is also conservative, but he confesses that he is himself old-fashioned enough to put more trust in the trained digital sense of the expert ophthalmic surgeon, coupled with accurate fundus and field examination than in any tonometer. The fact of abnormally high tension being established, the difficulty remains of determining whether the glaucoma is primary or secondary. The presence of keratitis punctata establishes the diagnosis at once, but often, in the presence of a glaucomatous haze of the cornea, it is impossible to be sure whether or not it is actually there. The point is of vital importance because in primary glaucoma the first essential in treatment is to insert a miotic; in glaucoma, secondary to iridocyclitis, such treatment will probably make matters worse and a mydriatic may be indicated. The depth of the anterior chamber is a most important point in diagnosis, but a shallow chamber is not enough by itself to determine that the glaucoma is primary. Mr. Greeves expresses the view that some of the cases of congestive glaucoma with shallow chamber may be a mixture of primary and secondary glaucoma. In deciding on the treatment of such a case, the depth of the anterior chamber is of primary importance; if it is deep a mydriatic may be used with benefit and impunity, but if it is shallow, shallow miotic treatment is indicated.

Many other aspects of the glaucoma problem are discussed in this interesting lecture. Mr. Greeves divides primary glaucoma into two main groups: the first comprising cases of acute, subacute, and chronic subacute glaucoma, with either pain, rainbow haloes, or misty vision; the second includes chronic simple cases with no subjective symptoms beyond gradual failure of vision and field, the patient being often unaware that the vision of one eye is gone until the other begins to go. In the first, or congestive group, a strenuous attempt should always be made to reduce the tension by treatment before an operation is undertaken; the prognosis after operation as regards visual acuity, he says, is infinitely better "if one has succeeded in reducing the tension beforehand than if one is forced to operate on a congested hard eye, quite apart from the danger of convulsive hæmorrhage." The details of treatment, both non-operative and operative, set out by Mr. Greeves, are well worth study, as is also the section on diagnosis by field and disc examination of cases of simple chronic glaucoma, in some of which even raised tension may be absent at the actual times when the consultation takes place. His comments on the causation and pathology of these cases are original and important. He believes firmly that the true explanation of simple glaucoma is failure in function on the part of the filtration angle of the anterior chamber, and in this connexion recalls an observation of Mr. Thomson Henderson's that the fibres that lie between the root of the iris and Schlemm's canal normally undergo a thickening as age advances, thus tending to obstruct the channel through which the aqueous finds a normal exit, and so predisposing to glaucoma during advancing age. The weak point of Henderson's theory appears to be that if it were true presbyopes should be much more subject to glaucoma than they are in practice. Mr. Greeves supplements the theory by the suggestion that in some people a congenital anomaly may cause these fibres to be unusually tough, or that the process of thickening may be abnormally hastened during the presbyopic period.

To the older men who learnt ophthalmology at Moorfields it will thus bring some satisfaction to learn on the authority of a well-known member of the present staff that the teaching that they received in their student days on glaucoma is not yet entirely superseded.

STUDIES IN HAY-FEVER

SEVEN original articles on hay-fever are to be found in *Nordisk Medicinsk Tidskrift* for June 1st. The first of them, properly enough, is a historical retrospect and an Englishman enjoys pride of place in it. But since Bostock presented his report on hay-fever to the Medical and Chirurgical Society in London in 1819 much has been learnt of this disease, and it is now remarkably amenable to specific treatment provided doctor and patient exercise foresight and patience. This is, at any rate, the opinion of Prof. K. Hansen, of Lübeck. He claims that with prophylactic subcutaneous injections of pollen antigens he has succeeded in curing or relieving over 90 per cent. of the 961 patients treated in 1932 and 1933. During the past four years he has used a mixed standard preparation containing extracts of all the pollens found to be pathogenic in Central Europe; and though he deplores his departure from the narrow road of strictly specific treatment—according to which he should inject only that antigen which skin tests have convicted for the particular case—he has found material considerations an irresistible inducement to the use of polyvalent mixtures. Only when these fail does he recommend a special search for some rare pollen antigen as a cause of hay-fever. The journal also contains a study by Dr. P. Vallery-Radot and Dr. G. Mauric, whose work in Paris on asthma and hay-fever has centred on their reactions to artificial fever. Their thesis, which they support with details of an illustrative case, is that above a certain thermal threshold asthma and hay-fever can be aborted by fever, and that immunity to offending pollens can be acquired if, during an attack of artificial fever, the patient is made to inhale such pollens in large quantities. The preparation with which they have induced fever is a 1 per cent. solution of sulphur in oil, 2 c.cm. of which is given by intramuscular injection. In the case in question immunity to hay-fever was promptly acquired by this measure, the patient remaining free from oculo-nasal symptoms for the rest of the summer. In another paper, Dr. K. H. Baagöe of Denmark refers to his experience with 52 cases of hay-fever, and to the effects of prophylactic injections of an extract of pollen given twice a week for two months before the hay-fever was due. Considerable benefit was obtained in 14 cases, and none in 6. Dr. Arno Saxén of Helsingfors draws attention to the remarkable rarity of severe hay-fever among his compatriots in Finland, but is able to suggest no explanation of it.

LEAGUE OF NATIONS AND NARCOTIC DRUGS

THE advisory committee on traffic in opium, at its twentieth session under the chairmanship of Dr. Carrière, the representative of Switzerland, reviewed the present situation in regard to the international traffic in dangerous drugs. While it is claimed that the licit production of narcotics now approximates to the legitimate requirements of the world, illicit traffic has not diminished and clandestine manufacture is going on both in the West and in the East. More drastic measures, such as the appointment of special police to track down clandestine factories, the infliction of heavier penalties for traffickers, and better international coöperation were considered and referred to the Secretariat for report to the next meeting. It appears that only three countries of Latin America have this year furnished reports required under the conventions. The Limitation Convention of 1931 has now been ratified by 53 governments, recent signatories being New Zealand, Japan, Panama, and Ecuador. As regards China, Mr. Hoo Chai Tsai reported new regulations adopted in April, 1935, whose Draconian severity appears to have shocked some of the delegates. There is to be compulsory treatment for drug addicts; if in 1936 there are any remaining untreated they will be imprisoned for five years and undergo the compulsory cure. After 1937 the penalty for the non-medical use of narcotic drugs will be death or imprisonment for life. The use of opium prepared for smoking is to cease by 1938. It was reported that more than 597 special hospitals for smokers and addicts had been established by the government in China; and it was claimed that no fewer than 81,344 cures had been already effected. Poppy cultivation is to be prohibited in some provinces and reduced in others until, in six years' time, it is hoped that it will be completely abolished. Those who recall the previous efforts in this direction some seventeen years ago, and the subsequent regrettable reversion to the extensive cultivation of the poppy, may regard these anticipations as over sanguine, while recognising the good intentions of General Chiang Kai Shek and the Chinese Government. Meanwhile the Japanese Government has authorised Dr. Somei To to report on 150,000 opium smokers in Formosa and the mortality and criminality of such addicts. The statistical results are receiving the attention of the advisory committee.

The Permanent Central Opium Board also met in Geneva last month, under Mr. Lyall's chairmanship, and discussed the legal position created by the production of morphine from "poppy straw." They invited the views of the advisory committee on the new situation which has thus arisen.

RADIOLOGICAL DIAGNOSIS IN THE ACUTE ABDOMEN

Dr. Irving W. Ponemon,[1] of Jamaica, is convinced of the importance of X ray examination in the differential diagnosis of the acute abdomen. He contends that its use is an additional safeguard against such serious errors as the performance of laparotomy for the abdominal pain which accompanies the onset of some cases of pneumonia; delay in opening the abdomen in the less typical cases of intestinal obstruction or perforation of ulcers; and confusion of the generalised pain of coronary thrombosis with that of perforation of a viscus. He cites examples where radiology has been of definite value. The histories of two children are contrasted, each aged five years. The onset of illness in both was with a cold, abdominal pain and vomiting appearing four or five days later; both children were found to have abdominal rigidity, and no signs in the chest were discovered in either. In one child the X ray showed evidence of commencing consolidation at the right base, while in the other child it was negative. The second child was submitted to operation when perforation of an inflamed appendix, with peritonitis, was found; the first child recovered from its pneumonia. In another case, quoted by Ponemon, radiology disclosed an unsuspected subphrenic abscess as a complication of cholecystitis and calculus, thus materially affecting the operative procedure. The localisation and appearance of distended coils of intestine can give valuable information. In one instance, distended coils in the lower right quadrant of the abdomen clinched a rather uncertain diagnosis of appendicitis. Gaseous distension with fluid levels underlying the collections of gas provides a sign almost pathognomonic of intestinal obstruction; but Ponemon believes that it is possible to detect in an X ray the evidence of a localised distension of a *single* loop in the early stages of an obstruction, thus giving the patient the chance of early operation. The appearance of a collection of gas under the dome of the diaphragm is, of course, a most useful piece of evidence in the detection of a gastric or duodenal perforation; especially in a case seen either during the stage of reaction (when all pain may temporarily disappear) or when, as a rare occurrence, the perforation has sealed over, leaving the diagnosis resting on a rather indefinite history. Where the possibility of coronary thrombosis is under consideration in the differential diagnosis of perforation, the importance of the demonstration of the presence of free gas in the abdominal cavity is obvious.

The main drawback to the use of radiology in these acute illnesses is the extra strain it puts on the patient. An X ray in the supine position is almost always possible, but for the detection of fluid levels and for the examination of the diaphragm the upright position is usually necessary, and experience shows that this may involve considerable difficulty. Ponemon considers the sitting position satisfactory; but this may give a very imperfect picture of the abdominal cavity, as the plate has to balance on the patient's lap. In most cases the disadvantages of submitting the patient to the strain of a radiological examination may outweigh the advantages, but the possibility that such an examination may clinch a difficult diagnosis should be remembered.

COLOUR VISION

An important contribution to the study of colour and colour vision has just been published by the Medical Research Council.[1] The abundant literature on this subject mostly deals with qualitative investigations and results; in this research by Mr. F. H. G. Pitt, which represents a continuation of the work of Mr. L. C. Martin, D.Sc., and Mr. W. D. Wright, Ph.D., at the Imperial College of Science and Technology, it is the quantitative factor which has been particularly studied, with fruitful results. The apparatus used was a slightly modified form of the Wright colorimeter—an apparatus of a high degree of accuracy, designed by Dr. Wright and used by him in his redetermination of the trichromatic mixture data,[2] and the object was to determine the colour coefficient, luminosity, and hue discrimination data for dichromatic observers and to compare them with those for normal observers.

In the first investigation the red and blue primaries were used for deuteranopes, and the blue and green for protanopes, the data of these latter being transformed for comparative purposes so that the coefficients were referred to blue and red primaries; this was deemed necessary owing to the low degree of protanopic luminosity at $0{\cdot}65\,\mu$. The colour standard was a spectral colour at $\alpha = 0{\cdot}494\,\mu$, the units being so chosen that the colour had equal amounts of each primary. The energy source was a standardised 1000 watt gas-filled lamp, the modified beam being reflected into the field from a white magnesium oxide screen. The eyes of the observers were dark-adapted before experimentation and each match was repeated three times.

The two main curves for the protanopic and deuteranopic groups are very similar, the only difference appearing from about $0{\cdot}51\,\mu$ to the red end of the spectrum. It was found that the blue coefficient for the standard white is greater for the protanope than for the deuteranope; and by deduction, that all colours possible to dichromatic vision can be seen by dichromats in the spectrum. In the determination of luminosity data measurement was made of the luminosity curve of the ordinary spectrum, and of the spectral energy distribution; and the luminosity curve for an equal-energy spectrum was calculated. For the first investigation a flicker photometer was used with light from the blue primary only, flicker being eliminated by means of a neutral wedge. The separation of protanopes and deuteranopes by this means was quite distinct, overlap of even the extremes of each group not occurring except from $0{\cdot}48\,\mu$ to the violet end. For the complete calculations and results of the remainder of this part of the investigation reference must be made to the report.

The measurement of hue discrimination curves was based on experiments in which by slow movement of the test colour prism in each direction the two halves of the field were made just perceptibly different; half the difference beteween the readings gave one colour step, allowance being made for variation in the length of the steps throughout the spectrum. It was found that the curves of six deuteranopes formed a well ordered set, whereas the protanopic curves were not so consistent; the mean curve for this group does not therefore represent the average so accurately as does that for the other group. The conclusions reached were that the discrimination of the deuteranope and the normal trichromat is approximately the same in the blue-green, and that the discrimination of the protanope is not so good as that of the deuteranope, nor is his range of discriminable colour so large.

In the remaining sections of the report consideration is given to saturation, qualitative tests, the work of previous observers and the theoretical considerations in connexion with colour vision, together with the bearing of the present dichromatic measurements on these theories. From a consideration of colour triangles the conclusion is reached that deuteranopes can distinguish only 15 colours, and protanopes 12, when the intensity is uniform, the corresponding figure for a normal trichromat being 43. Moreover, if 500 trichromatic colours were included the number for the dichromat would only increase very slightly. In an appendix Mr. Pitt records the results of an investigation of anomalous trichromats (those whose colour system is a function of three variables but whose matches differ from the normal). The investigation was done on green anomalies only, and no definite conclusions are drawn. Another appendix, by Dr. Wright, is concerned with the advisability of regarding the eye of the normal and colour-blind observer as two entirely unrelated pieces of apparatus, and with the position of the anomalous trichromat relative to the normal trichromat and the dichromat.

The value of the information here set out is, as Dr. Wright says, twofold. It enables us to determine exactly by how much one colour will differ from another, and understand the extent to which colours that appear distinct to the normal eye will be confused by the so-called colour-blind eye; and it also provides us with further material on which to develop a theory of colour vision and colour blindness.

NUTRITION AND LEPROSY

The fact that *Bacillus* (or *Mycobacterium*) *lepræ* does not fulfil Koch's postulates has at times given rise to much discussion of its ætiological significance. Few will now be found to dispute its claim to be the cause of the disease, but clearly there are many other factors which play an important part. It is almost an axiom that the healthy adult does not acquire leprosy unless he comes into close and very prolonged contact with the disease, and if he does his resistance probably has to be lowered before dissemination of the organism is clinically manifest; but the same rule does not apply to children and adolescents, because there seems to be an added susceptibility during the growing periods of life, when metabolic activity is at its height. How far the risk is affected by diet is a question that has long been debated. Sir Jonathan Hutchinson, it will be remembered, laid the whole responsibility on putrid or badly cured fish; he said that "the fundamental cause in the malady known as true leprosy is the eating of fish in a state of commencing decomposition."[1] Like many others which contain an element of truth, this theory was widely quoted, and since Hutchinson's time workers have constantly laid stress on the need for a proper diet. A recent observation by Atkey[2] is that the milk-drinkers of the Sudan have very little leprosy. Again, it is known that the incidence of leprosy is much higher in South Korea, where the diet consists chiefly of carbohydrates, than in North Korea. It is the lack of a balanced diet, with associated vitamin deficiency, that appears to be of greatest detriment, and it is interesting to note that, other things being equal, there is usually a high incidence of leprosy among people who subsist on a diet containing excess of carbohydrate—e.g., the cassava-eating people of the southern Sudan. Recently Lee[3] has drawn attention to a reduction of gastric acidity in leprosy, pointing out that the more severe and long-standing the skin lesions, the more definite the hypochlorhydria. It must be borne in mind, however, that leprosy, especially the cutaneous variety, is a systemic disease and that where the skin is involved the bacilli have invaded the whole reticulo-endothelial system, producing lowered resistance of the whole organism. This process must lead to more or less cachexia, and it seems probable that Lee's findings could be explained as due to general decline in bodily functions, and that low acidity should not be invoked as a cause of the nutritional failure which encourages infection by the leprosy bacillus. If light could be thrown on the reasons for the dissemination of the bacilli through the body, it might be possible to raise the resistance of the patient appropriately and so check the progress of the disease. Meanwhile it can hardly be doubted that an adequately balanced diet with suitable content of vitamins does much to improve the chance of recovery.

DR. JOSEPH HUNTER, M.P.

WE regret to learn of the death, on Tuesday last, in Charing Cross Hospital, of Dr. Joseph Hunter, the well-known Liberal M.P. for Dumfriesshire. Dr. Hunter was that admirable type of medical Member of Parliament who had seen the working of medicine reflected on general society in numerous official capacities. He graduated in medicine at Edinburgh in 1898 and became resident physician at the Royal Infirmary, Edinburgh, when he joined the South African Field Force as a civil surgeon, gaining the Queen's medal with clasps, and showing himself a highly competent officer. Thereafter he took the diploma of D.P.H., and served as medical officer of health and police surgeon to the borough of Dumfries, and was also physician to the Dumfries and Galloway Royal Infirmary. After 20 years of official medical work he entered Parliament as the Liberal Member for Dumfriesshire in 1929, displacing with a great majority the sitting Conservative Member. At the next General Election he held his seat against a Liberal opponent, and this time with a very large majority, a clear example of the recognition by a large community of the value of his local services, and of the ability with which he fulfilled his responsibilities. In 1929 he became the Scottish Liberal Whip, and in 1934 was appointed organiser of the Liberal National Party. Dr. Hunter will be deeply missed from the circle of politics where he played so prominent a part as well as by many friends and colleagues.

THE NEUROLOGICAL CONGRESS

ON Monday next the second International Neurological Congress opens in London under the presidency of Dr. Gordon Holmes, F.R.S. Sir Charles Sherrington had been elected at last year's preliminary conference, but was unable to undertake the arduous duties on grounds of health. The congress sits in the large hall of University College, Gower-street, from Monday to Friday, the morning sessions being devoted to set discussion of four main topics: (1) Monday (morning and afternoon)—The epilepsies, their ætiology, pathogenesis and treatment (chairmen, Prof. O. Marburg and Prof. O. Rossi). (2) Tuesday—The physiology and pathology of the cerebro-spinal fluid (chairman, Prof. O. Foerster). (3) Thursday—The functions of the frontal lobes (chairman, Prof. H. Claude). (4) Friday—The hypothalamus and the central representation of the autonomic system (chairman, Prof. B. Brouwer).

At the three afternoon sessions, which will sit in seven groups, nearly 300 papers will be presented. On Wednesday evening at 9 Prof. Foerster will give the triennial Hughlings Jackson memorial lecture (on the Motor Cortex in Man in the Light of Hughlings Jackson's Doctrines) under the auspices of the section of neurology, Royal Society of Medicine, and this section will hold a reception later in the evening. Other receptions will be held by the Ministry of Health and the presidents of the Royal Colleges. The official banquet is on Thursday evening at Grosvenor House. Wednesday has been left free. The secretary-general of the congress is Dr. Kinnier Wilson.

THE Princess Royal has appointed Dr. L. F. R. Knuthsen, C.V.O., to be her physician-in-ordinary.

THE death is announced of Mr. Arthur Shillitoe, F.R.C.S. Eng., a well-known authority on syphilis.

THE peerage conferred upon Sir Hilton Young in the Birthday Honours is gazetted under the title of Baron Kennet, of the Dene, in the county of Wiltshire.

NEW SUSSEX HOSPITAL FOR WOMEN AND CHILDREN.—The latest addition to this hospital, which was the first in the country to be entirely officered by women doctors, is a nurses' home which is being erected in the grounds on the west side, and it is hoped that the completed building will be opened in November. The foundation stone was laid on July 18th by Miss Louisa Martindale, who said that it was an unusual task for a member of the honorary medical staff but she accepted it as a mark of appreciation of the hospital's medical and surgical work and of honour to her mother, the founder of the hospital. Her mother realised the demand there was in Sussex for a hospital in which women patients could be treated by members of their own sex, and foresaw how long they would have to wait if they were to depend upon the existing hospitals appointing women to their staffs. The hospital is open to professional and other women of small means who are unable to pay the expensive fees of a nursing home.

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXII.—PROGNOSIS IN HEART-BLOCK

HEART-BLOCK is the term used to indicate a disorder of the function of the heart, notably imperfect conduction of the impulse. The term includes several types of disturbed function of varying degrees of severity, occurring in different sites.

From the point of view of prognosis one can exclude *sinu-auricular block*, which is extrinsic in origin, being due to depression of the formation of impulses at the sinu-auricular node by an increased vagal tone. Thereby the rate of the heart may be halved; but there is no prognostic significance to be attached to this aberration, which is wholly nervous in origin, and not indicative of myocardial disease. *Intra-auricular* block is not recognisable clinically. There remain: (1) *Auriculo-ventricular block*—(*a*) partial, with or without dropped beats; (*b*) complete heart-block. (2) *Intraventricular block.*

IMPORTANT FACTORS

The prognosis of heart-block in general must be considered with two points in mind: (1) the functional efficiency of the heart in which the lesions are found; (2) the liability for auriculo-ventricular block to be associated with syncopal attacks (Adams-Stokes). Many patients die from heart failure without developing heart-block at all; and some patients live for years with heart-block, and finally die from some condition that has nothing to do with the heart. Heart-block may be due to some local lesion; it may only be evidence of inefficiency in one small part of the heart, and this particularly applies to auriculo-ventricular block. On the other hand, the local lesion may be a part of general myocardial disease. In the assessment of prognosis, the efficiency of the heart as a whole in its response or lack of response to extra demands made upon it is the real ground upon which the prognosis must be based. It is necessary to emphasise the fact that the search for one particular prognostic sign may easily lead to fallacy. Heart-block when present must be fitted into the clinical picture and not singled out for too much attention. Its importance varies to some extent with its ætiology, in so far as this may have a bearing upon the presence or absence of general myocardial disease.

Partial heart-block without dropped beats can only be recognised with certainty by graphic methods. Dropped beats may usually be detected by auscultation, except when the rate of the heart is fast, and the varying degrees of delay in auriculo-ventricular conduction, together with numerous dropped beats, may make diagnosis difficult owing to the very irregular rhythm produced. Partial heart-block does not in itself affect the efficiency of the heart unless many beats are being dropped, when syncopal attacks may occur. In toxic conditions, such as diphtheria and rheumatism, it will probably clear up as the cause disappears. When syphilis is the cause the prognosis is apt to be influenced by the grave effects that accompanying aortic lesions may produce. In such cases there is considerable liability for higher grades of block to be set up, and Adams-Stokes disease (see below) may supervene. In elderly people, where arterial disease is almost always the cause, the degree of block may remain unchanged for years. But in some cases there is a tendency for the block to increase as the disease progresses. When auricular fibrillation is present, a certain amount of auriculo-ventricular block may be an advantage, for it will keep the ventricular rate slow without the use of digitalis.

Complete heart-block is usually easy to recognise clinically, especially if the patient's heart-rate be tested by injection of atropine, or if he can be exercised. The failure to respond by marked increase in rate is pathognomonic. Complete heart-block is not always associated with gross incapacity, and does not necessarily carry a bad prognosis, especially if Adams-Stokes attacks are absent. In some cases the rate, which may vary between 30 and 55 beats per minute, is not very slow, and is compatible with a fair degree of efficiency. Some patients live for years if no other signs of defect develop. In most cases, however, there is also widespread disease which causes heart failure.

Congenital complete heart-block is a rarity, and is usually associated with patency of the interventricular septum. The rate of the ventricles is usually faster than in the acquired lesion. Provided the septal defect does not affect the function of the heart unduly, those patients are often able to be fairly active and grow up to adult life. As is the case with all congenital lesions, secondary infections at the site are apt to occur.

Intraventricular block, which means delay or block in one or other of the two branches of the bundle of His, or delay in the spread of the impulse over the Purkinje system, can only be demonstrated by an electrocardiogram. Intraventricular block when present as bundle-branch block does not necessarily indicate anything but a local lesion. But mostly there is widespread disease as well. The efficiency of the heart is not affected by the local lesion in the branch of the bundle itself. Some patients survive and even lead an active life for years, but on the whole the association of myocardial disease with intraventricular block is not propitious, and those who show signs of heart failure only last a year or two. The same outlook applies to the type of curve denoting intraventricular block in the Purkinje system. Here again the majority of patients are suffering from gross lesions with more or less impaired efficiency. For the most part failure is likely to occur soon, and when it shows itself a short span of life is all that can be expected.

THE ADAMS-STOKES SYNDROME

The sudden loss of consciousness characteristic of Adams-Stokes attacks may manifest itself when first the obstruction in the bundle of His is complete, and there may be a pause before the ventricles beat with their own slow rhythm; again, when the block has already been present for some time, interference with the activity of the new pacemaker may cause extreme slowing or standstill. These attacks are dangerous for two reasons. The standstill may lead to sudden death, or the fall, without warning, in some dangerous place or in traffic, may give rise to serious injury. But the liability to these attacks may be transient, and once the patient is free from them they may not recur. Their incidence may, moreover, be warded off successfully by adrenaline or ephedrine in appropriate dosage. Very frequently dropped beats should suggest the possibility of the onset of complete block with a liability to Adams-Stokes attack.

SUMMARY

To sum up then, the prognosis in heart-block depends on its cause and the degree to which the associated lesions produced by this cause affect the efficiency of the heart. The liability to ventricular standstill carries a very grave prognosis of its own. Such a sign as heart-block affords too narrow a basis when taken by itself upon which to give a prognosis. But it may provide valuable evidence of the presence of myocardial disease which might otherwise be overlooked, and its presence adds an unfavourable point to the outlook in any case where it is found.

TERENCE EAST, M.D., F.R.C.P.,
Physician, King's College Hospital and Woolwich Memorial Hospital.

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION

PROCEEDINGS OF THE REPRESENTATIVE BODY

THE Representative Body met in London on July 19th, 20th, 22nd, and 23rd under the presidency of Mr. H. S. SOUTTAR.

Sir JAMES BARRETT (Melbourne) was elected president for 1935–6, in consequence of the death of Sir Richard Stawell, and Sir Farquhar Buzzard to the same office for 1936–7. Prof. T. G. Moorhead, Dr. R. Langdon-Down, Dr. R. H. Fetherston, and Dr. W. N. Robertson were elected vice-presidents, Sir Farquhar Buzzard, who was received with loud applause, acknowledged the honour and welcomed the Association to Oxford next year. Sir J. H. MacFarland and Sir Edward Mitchell were elected Honorary Members in commemoration of the first meeting in Australia.

Subscriptions from Retired Members

The hon. treasurer presented a satisfactory balance sheet, which called forth no criticism, but under this heading Dr. B. H. PAIN (Tunbridge Wells) likened the Association to a leaky watering can from which old members trickled out as fast as new ones came in; thus the can remained half full. His remedy was to reduce the subscription for those retired from practice, and he supported his motion by adducing replies to a questionnaire sent to non-members in Kent. The old men of the profession, he said, could give much to, and gain much from, the Association. A long series of speakers concurred, but Dr. A. BEAUCHAMP said that a questionnaire in Birmingham had shown only 10 per cent. of non-members to be aged. The hon. treasurer's statement that Kent's "sob-stuff was not real" evoked protest, but he declared that the Association lost only seventy members a year from retirements and nearly all those who retired in any part of the country apparently went to live in Kent. Dr. MURRAY (Banff) retorted that he did not come from the Garden of England and yet found the same problem, and he supported the motion. "Once a member aye a a member" should, he thought, be the Association's motto. The difficulty, said the Chairman of Council, was to decide when a doctor retired, but Dr. Pain saw no such difficulty, and added, amidst applause, that in any case the Council had been elected to overcome difficulties. The Tunbridge Wells motion asking the Council to consider charging retired members less than the present two guineas was then passed by a very large majority.

"The British Medical Journal"

Dr. R. G. GORDON presented the report of the journal committee over which he presides. Improvements in the *Journal* were of the greatest importance to the whole Association, and might have an influence on membership. Most important was the attraction of the young man into the profession. He should be given a journal which he could not afford not to take, a journal considering general attractiveness of make-up and lay-out as well as other matters. The committee had tried during the year to improve appearance by bolder headings, more cross-headings, and better grouping. Many other changes were in contemplation. Next year a revolutionary programme might be presented.

Torquay, by the mouth of Dr. ERNEST WARD, asked the Council to consider the advisability of devoting part of the *Journal* to matters of interest to junior and senior students. Some of the prize essays might be published, and more reference given to student affairs, such as athletic prowess and history-making.

Dr. GORDON said the *Journal* was primarily for practitioners. More matter was available than could be published, and the *Journal* was hardly the proper vehicle for athletic reports and student activities. (Hear, hear.) The motion was rejected.

Dr. HELEN LUKIS (Kingston-on-Thames) proposed:

> "That the items advertised in the *British Medical Journal* under Houses, Consulting Rooms, &c., should be confined to consulting rooms in bona fide consulting areas: houses sold in connection with an existing practice, nursing homes, residential chambers and general advertisements of house agents: and that advertisements of single houses should not be accepted unless coming under one of these categories."

She said that the motion was the result of grievances by six separate doctors, and related the incidents. She asked who would lose if the resolution were passed, and suggested that the medical man with inadequate capital and the patients in newly-built areas would not be among the losers. Squatters who built up a practice for sale were far too shrewd. Those who came to stay made careful inquiries before settling. Those who came and starved came as the result of answering such advertisements. The *Journal* ought not to lead people up the garden path like that. The loss of revenue to the *Journal* would be very small. The *Journal* was not published for the benefit of advertisers.

Dr. N. E. WATERFIELD (Kingston) supported. He had seen an advertisement of a house in his own small village, which was already well staffed by doctors, who would have had a grievance if someone had been attracted there.

Dr. E. H. NASH (Hounslow) said the matter needed consideration. Some areas were increasing at the rate of 10,000 a year; an advertisement offering a house in such a district did not hurt practitioners already there. It was not dignified to try to keep out all newcomers. Some kind of warning notice might meet the case.

Dr. GORDON expressed sympathy with the motion but agreed on the need for caution. Advertisements were not passed without a good deal of consideration wherever time allowed. He asked Kingston to refer the matter to Council. As it stood, the motion might preclude the advertisement of a death vacancy. Kingston accepted this modification and the meeting agreed.

"Secret Remedies"

Sir Ewen Maclean, chairman of the science committee, moved the adoption of its report. The sum of £1000 was, he said, distributed annually in the encouragement of research, and he hoped the sum would be increased. The tendency had been to shift the value from grants to scholarships, and this had been justified by the quality of the applications received. The Association was very fortunate in its Library and the chairman of the Library Committee (Dr. C. O. Hawthorne). Its arrangement with the National Central Library bestowed very wide possibilities on borrowers. The Sir Charles Hastings and Stewart prizes had been awarded this year to Australasian members.

Newcastle and West Dorset both applied for a new edition of "Secret Remedies." Dr. A. Hedley Whyte (Newcastle) pointed out that the latest edition was dated 1912 and yet was still of use. There was an ever-increasing number of proprietary remedies about which patients frequently asked. Dr. J. A. Pridham (West Dorset) admitted the difficulties of keeping the book up to date and suggested an annual supplement. Dr. E. N. Nash spoke strongly of the ramp of the patent medicine service in this country and of the value of "Secret Remedies" to the practitioner. But Sir Ewan Maclean said the book had not served the purpose for which it was issued and he thought its re-issue would be very inadvisable at the moment. The Chairman of Council emphasised the difficulties of a new issue. He thought some system of differentiation between valuable and worthless secret remedies was very desirable, and said that this possibility was already being explored by a joint committee of the Association and the Pharmaceutical Society. He persuaded the meeting to reject the motions of Newcastle and West Dorset by a small majority.

The British Medical Bureau

Several divisions had on the paper motions disapproving of the relation of the Association with the British Medical Bureau and regretting that body's custom of advertising in the lay press and of allowing commissions. After prolonged discussion in private these motions were lost and the Representative Body recorded its confidence in the directors of the Bureau and its approval of their conduct of the business.

Nutrition—Alcohol—Fractures

The Chairman of Council said that the nutrition committee, over which he presided, had prepared a practical application of the Diet 16 recommended in the Nutrition Report. This publication taught the housewife how to buy, cook and serve the diet advised, and would have wide social consequences. Dr. H. H. MacWilliam (Liverpool) asked if practitioners in distressed areas would be justified in certifying the need for additional nourishment for any person unable to afford this diet. Dr. Nash and Dr. A. K. Gibson (Kensington) thought mismanagement was more important than poverty and laid stress on the amazing amount of waste.

Dr. W. G. Willoughby (Eastbourne) told the Representative Body that a report had been drawn up on the relation of alcohol to road accidents, and would shortly be printed in the journal.

Dr. H. G. Dain took the chair while Mr. H. S. Souttar submitted the report of the fractures committee[1] and emphasised again the fell consequences of discontinuity of medical responsibility.

Mr. McAdam Eccles emphasised the waste of human value and money caused by inadequate treatment of fractures. Dr. R. M. Picken was with him in hoping that the recommendations would be put into force, and mentioned the service the divisions might give in this connexion by bringing pressure to bear on local authorities and voluntary hospitals.

Mr. Souttar having returned to the chair, the Chairman of Council referred to the committee appointed to deal with the physical education of the civilian population and the half-dozen sub-committees dealing with special aspects of this problem. He anticipated that the report would appear early next year and would be of the greatest public value.

Dr. R. G. Gordon countered a complaint by Dr. J. S. Manson (Warrington) that no further account had been given of the activities of the committee on the Medical Aspects of Abortion. Much information had, he said, been collected but a report of adequate measure required more time and more data.

The Report of Council on all these matters was approved.

Mr. H. S. Souttar and Dr. H. G. Dain were elected unopposed as chairman and deputy-chairman respectively of the Representative Body.

Medico-political

A long discussion, which was held in private, took place on the dispute at Llanelly. In the result, a motion was passed expressing confidence in the Council but asking it to continue to strive for a satisfactory solution of the difficulty.

A long discussion took place on the medical services in Llanelly and district, and eventually the following resolution was unanimously approved by the meeting:—

> That the Annual Representative Meeting expresses confidence in the Council, and instructs it to continue to use every endeavour to secure a satisfactory settlement of the dispute at Llanelly.

South-West Wales asked the meeting to deprecate the practice of insurance companies in demanding complicated medical reports in sickness and accident claims with a view to using information so obtained as grounds for refusing renewal of insurance when the time came. Moreover, the patient had to pay. Dr. Bone, chairman of the committee, said the problem was an old and familiar one, and asked what steps could be taken, except by propaganda. The motion was lost. The Isle of Wight also had complaints about insurance. Dr. H. S. Howie Wood contended that a simplified form of report and examination should be instituted for cases where only half a guinea was payable. Dr. Bone accepted this resolution, but could not do the same for the second proposal: that certificates on patients not previously examined should carry a minimum fee of half a guinea—a sum which Dr. C. E. S. Flemming (Council) wished to raise to a guinea. Dr. Howie Wood obtained permission to refer the matter to Council for consideration.

Dr. A. T. Jones (N. Glamorgan and Brecknock) felt that the Council had standardised a flat rate of a guinea for examination and report on workmen's compensation and accident cases, by its opinion that "the usual fee of £1 1s. for this class of work is equitable," and moved that a guinea should be the minimum fee. The motion was passed.

The vexed problem of the encroachment of whole-time medical officers on private practice was raised by Brighton. Dr. T. P. Mulcahy moved that:—

"Whether or not whole-time salaried medical officers appointed to mental hospitals by a local authority should be permitted to engage in private consultant practice should depend, not on the local authority having adopted the scheme on staffing of their mental hospitals outlined in the Memorandum on Treatment of Mental Disability (1932), but on whether or not there is available in the area of that authority one or more private medical practitioners who fulfil one or more of the three criteria adopted by the Association as determining the status of a consultant in psychiatry. When there is such a private practitioner or practitioners available, then whole-time salaried medical officers should not engage in private practice."

---

[1] See The Lancet, 1935, i., 383 and 393.

Dr. L. A. PARRY explained that what Brighton wanted was to ensure that if a private psychiatrist was available in an area he should not come into conflict with a whole-time officer. Dr. GORDON expressed sympathy with the motion but pointed out the number of areas where no private expert in mental disease was available. The amendments proposed in the Council's report were the result of discussion with the Medico-Psychological Association. He was reluctant to upset this arrangement, but agreed with the principle. He suggested that a later motion on the agenda would establish the principle without necessitating further discussion with the Royal Medico-Psychological Association. Brighton, touched by his assurances and appeal, withdrew its motion.

Dr. R. EAGER, for Exeter, also wished to modify the Council's report on this matter by adding to it:—

> "In considering the eligibility of a practitioner for one of these appointments, the criteria to which due regard should be given are: (1) Special academic or post-graduate study combined with some actual practice of the specialty; (2) Tenure of hospital appointments affording special opportunities for acquiring experience; (3) Local professional recognition of competence in a consulting and expert capacity; and that para. 52 be amended by the deletion of the words 'are adequately qualified to staff such clinics' and the substitution therefor of the words 'satisfy the criteria set forth in para. 48 V.'"

The report, thought Dr. Eager, gave an impression that six months' instruction was sufficient to qualify a man to treat mental disorder; when he had joined a mental hospital staff he had been told that five years' experience was essential. Dr. GORDON felt that all this was covered by the original words "adequately qualified," but was willing to make the matter explicit if desired. Coöperation was the great essential until such time as it was no longer necessary to use whole-time salaried officers in psychiatric clinics at all. He accepted the motion.

The New Contract Practice

Dr. KEITH GIBSON (Kensington) said that those who were working the public medical services wanted facilities for meeting and discussion, and proposed a motion asking the B.M.A. to provide such facilities. Medical men should be in a position to put things right before a Government department took over any service and not several months later. He received strong support from Dr. S. WAND (Birmingham), who stressed the great expansion of public medical services, and from Dr. HELEN LUKIS (Kingston) who described these services as one of the youngest babies of the B.M.A., cherished by the younger members of the profession who urgently needed advice and help. Dr. BONE doubted if this were a good method of attaining the end desired. The central office had very complete information on the matter, available to any member; existing services were very willing to give help and information; and this proposal was cumbrous and costly. How many of the 51 existing services would send delegates to a conference? He asked for reference to Council if the meeting, nevertheless, wished a conference called. Dr. A. MCCARTHY (Birmingham) denied that the central office had full information; all it had was a record of the mistakes made by individual officers in isolated districts. Dr. HOWARD STRATFORD (Kensington) and Dr. A. GRAY (Wandsworth) thought that now was the time before more mistakes were made, and that a conference would be of great value. Dr. A. BEAUCHAMP (Birmingham) declared that the management of a young child could not wait the twelve months involved by reference to Council. Dr. PETER MACDONALD challenged Dr. Bone's statement that a conference would cost the Association anything. Dr. NASH declared that the policy advocated by Dr. Bone was that which had made a mess of the National Health Insurance Acts. "Damn the expense," he said, "if we want the job done." If public discussion was of no value, what was the representative meeting there for? Dr. C. H. PANTING recalled the early mistakes of the Essex public medical service and the similar mistakes being made by new bodies. Essex had helped 31 out of the 51 existing services. The motion was carried by a very large majority.

Wandsworth, South-west Essex, and Willesden all wanted to ensure that contract practice for persons with incomes over £250 should be a matter of local option. The Council, said Dr. F. GRAY, was still bound by a 15-year-old motion prohibiting contract service on this income level. Contract practice for these people had been approved at Bournemouth for every kind of service except that of the general practitioner. Another medical body proposed to extend the National Health Insurance scheme to the whole population; the B.M.A. had *at present no alternative scheme to offer.*

Dr. C. H. PANTING strongly supported the S.W. Essex motion, saying that contract practice was not a bad thing in itself if properly run. The borderland people needed some service to fit their needs. Dr. C. F. T. SCOTT, speaking for Willesden, said that his area had already drafted a scheme as the need was so manifest. The need was further emphasised by Dr. KEITH GIBSON, but Sir HENRY BRACKENBURY urged that the exact wording be left for very deliberate consideration by the Council. Dr. HOWARD STRATFORD, gallantly fighting in the last ditch, declared that there would be no private practice left if this motion were passed, and that the absolute necessity for it had not yet arisen. He found an ally in Dr. A. B. MURRAY (Banff), who was anxious that the terms should be national and not determined by the local profession. Banff believed that the private practitioner was the backbone of the nation, and was opposed to all contract practice. Nobody there would get a living if this motion were passed. He made an impassioned appeal to representatives not to let down those who strove to uphold the standards of practice, and not to become mere parts of the machine. "Show that you can think for yourselves," he concluded amidst applause, "and take the consequences." Dr. C. S. POOLER (Chesterfield) gave the same advice but urged the meeting to think not in terms of Banff but of the whole country. The resolution binding the Council was dated not 1920 but 1913. Contract practice was not good for patient or doctor, but in the last ten or fifteen years most doctors had been obliged to treat persons over the £250 limit on a contract basis.

Dr. E. R. WALKER (Aberdeen) agreed that this was the beginning of the end but did not regret it. The laity regarded ill-health as a misfortune, and it seemed only logical that they should insure against this as against every other misfortune. He believed that they would never get a real preventive medicine practised until they had a contract system. He was supported by Dr. N. E. **Waterfield** (Kingston) and Dr. **Keith Gibson**, but Dr. C. J. **Palmer** (Nottingham) and Dr. A. C. **Carter** (Bournemouth) thought the motion a regressive one.

Dr. S. A. **Forbes** (Croydon) described the motion as allowing the Council to do in the future what it had done when it thought right in the past. Dr. **Nash** deprecated an attempt to pelt the incoming tide with pebbles of public opinion and preferred to dig channels for the water. Local option, he thought, would be a very dangerous thing, risking a whitling away piecemeal of the Association's strength. Dr. **Howie Wood** (Isle of Wight) maintained that general practice was what general practitioners made it. Those who opposed this scheme were forgetting that the Association considered the welfare of the public as well as that of the doctors. Conditions varied so tremendously that a flat rate was impossible. Dr. J. C. **Arthur**, of Gateshead, said that in his district people with £250–£500 a year were comfortably off and had something put by; they had no desire for a further extension of contract practice; 60 per cent. of them ran cars.

Sir **Henry Brackenbury** strove to clear up misapprehensions. Local option was not to be unlimited; the proposal was that the doctors of an area might apply to the Council to vary the rate of contribution. The usual conditions would apply in all general circumstances, and the matter concerned only voluntary contract schemes.

Finally the motion was carried by 108 votes to 37 (Dr. A. B. Murray demanding a count), in the form as proposed by Sir **Henry Brackenbury** and accepted by Wandsworth, Essex, and Willesden:—

> "That this Meeting instructs the Council to amend Minute 109 of the Annual Representative Meeting, 1920, so as to permit the Council to sanction a higher income limit, should the local profession desire it."

Dr. **Bone** proposed, and carried without difficulty, a proposal to amend the means whereby B.M.A. candidates for election to the General Medical Council are selected. The chief point about the new scheme, he said, was that in future it would be quite clear to everybody that the candidates were Association candidates.

The meeting then carried without discussion another motion by Dr. **Bone**, recommending the Council, pending the 1936 meeting, to treat as rescinded, two statements of Association policy on coroners' inquests: that the office of the coroner should be made administrative; and that the coroner should in all cases view the body. He said that the Council was preparing a statement of evidence to be given before the Departmental Committee on Coroners' Law.

Medical Ethics

Dr. C. O. **Hawthorne**, chairman of the central ethical committee, in moving the adoption of the committee's report, remarked that local authorities sometimes inserted in the lay press advertisements of appointments with conditions which disqualified them from admission to the *Journal*. In such cases the committee was now empowered to insert an appropriate notice in any paper which had printed an advertisement of a vacancy included in the *Journal's* "Important Notices." He also said that difficulty had been experienced by spa practitioners consulted by patients from a distance, since they could not consult with the local medical adviser and were therefore forbidden, on a strict interpretation of the Ethical Rules of Consultation, to treat the patients. To meet this position the Council had ruled that when a patient came to reside for a time at a spa, he should be considered to have left the care of his usual practitioner and the spa practitioner should be free to treat him—so long as the patient continued to reside at the spa.

Opticians

Mr. N. **Bishop Harman**, chairman of the ophthalmic committee, said in presenting its report that the increase in patients seen by the National Ophthalmic Treatment Board had only been 17 per cent. during 1934, but 27 per cent. in the first six months of the present year. Most of this increase had been among patients who came on their own and not from societies, showing that the committee's propaganda had been effective. Thirty-five per cent. of 10,000 patients had had something wrong other than refraction—a strong contrast with the corresponding figure of only 3 per cent. among those seen by opticians. A fresh set of 10,000 figures gave practically identical information, although it came from very scattered sources. They afforded statistical proof of several authoritative opinions that opticians failed to recognise ocular disease. He appealed eloquently to the profession to send their patients to properly qualified ophthalmologists. Some hospitals, he said, were entering into agreements with prescribing opticians, and it was imperative that this movement should be stopped. He deplored the complication of the current certificate of blindness.

Torquay, through Dr. E. **Ward**, put forward a resolution urging the Council:—

> "(1) To approach the Minister of Health by deputation or otherwise and to reaffirm the policy of the Association in this matter pointing out the danger to the eye-sight of patients who are sent to opticians without previous certification or examination, and to urge him to adopt measures which will safeguard the public against such risks.
>
> (2) To notify all contributory schemes, approved societies and such other bodies as make provision for sight-testing by opticians, offering them guidance as to the dangers of such treatment without medical training.
>
> (3) To advise strongly all hospitals lending their names to contributory schemes, which provide such optical benefit, to sever their connexion with such schemes.
>
> (4) To circularise the medical profession of the steps taken above."

Dr. C. M. **Stevenson** (Cambridge), however, said that the Council had already been doing these things for some time. It was largely dependent on local secretaries for the success of its efforts. Mr. Bishop Harman confirmed that the Council had "kept all these things from its youth up," and suggested a general motion of commendation, which the representative from Torquay adopted and which was agreed.

Dr. F. C. **Gittings** (Portsmouth) proposed a meeting of ophthalmic medical practitioners to discuss the difficulties of the Association's benefit schemes. Mr. **Bishop Harman** pointed out that a previous meeting of London ophthalmologists had not been a happy one, that a national meeting would be too large to hold in the great hall of the Association's building, and that the Ophthalmic Committee gave adequate territorial representation. The motion was rejected. He adopted an amendment by Sheffield that the fee for certifying blind patients should be not less than three guineas for a session of two hours.

Osteopaths

Dr. J. W. Bone presented for approval the report of the osteopathy committee, containing the evidence brought by the Association before the Select Committee of the House of Lords. He paid a special tribute to the very careful and exhaustive way in which material had been prepared by Dr. Charles Hill and the staff. The Association had organised and systematised the whole opposition to the Bill. The House of Lords had adopted unprecedented procedure in submitting a private Member's Bill to a select committee with leave for counsel to appear; heavy costs had thereby been involved. Dr. Bone read extracts from the Report of the Select Committee just issued (see p. 213), which appeared to give great satisfaction.

Mr. W. McAdam Eccles thought the Association might congratulate all concerned in this matter on being prompt and thorough and on doing a piece of work which would create history and do good to the rank and file of the profession. Good had been done also to the osteopaths themselves. Those who had a vocation for osteopathy would realise now that the best path for them was medical qualification and registration. The Chairman of Council explained how the machinery of the Association worked in these matters. The general feelings of congratulation and gratitude were expressed in a formal vote of thanks, which was carried with loud acclamation.

Public Health

Prof. R. M. F. Picken, chairman of the public health committee, moved the adoption of his section of the Council's report and discussed the special report on immunisation.[2] He also moved the adoption of the Council's recommendation that the Ministry and local authorities be urged to establish adequate machinery for collecting and storing convalescent serum for use in prophylaxis against measles. Practitioners, he said, could not obtain the serum from official sources or manufacturers, chiefly because the number of convalescents was so small and no adequate arrangements existed for collection. He asked for the coöperation of those in charge of adult patients.

Dr. A. K. Chalmers (Glasgow) accused the profession of playing a part in the failure of compulsory vaccination by giving way to the mother's plea for "ane mark and a wee ane." He thought the Association ought to play a part in educating the public. Dr. Nash desired to include "adult serum" in the recommendation. Parents, he said, often objected to the necessary quantities of blood being taken from their convalescent children, but he had obtained adult serum in adequate quantity and quality from Rover scouts. Dr. Picken, however, demurred on scientific grounds, as the action of convalescent serum was well known, and special machinery would be necessary to collect adult serum.

Dr. D'Ewart (Manchester) doubted gravely whether convalescent serum either was to be obtained in great cities or was as valuable in treatment as adult serum. Adult serum was easily obtainable in Manchester.

Dr. Chalmers moved a motion welcoming the report and asking that it be forwarded to each division. He said his object was to get divisions to combine and work on a uniform plan. The population would only submit willingly to vaccination in the presence of an epidemic, and better results would be obtained without compulsion.

Dr. Picken, moving the remainder of the report, thanked *The Lancet* and the *Journal* of the Society of Medical Officers of Health for coöperating with the *British Medical Journal* in the selection of advertisements of vacancies for publication. Much work was involved in seeing that these advertisements conformed to the requirements of the Association.

Midwifery in General Practice

Dr. A. Keith Gibson (Kensington), proposing that the Council should investigate the serious diminution of opportunities for midwifery in general practice, pointed out that the practitioner wished to do the work and found the chances very small, because large numbers of patients were absorbed by hospitals, not for the ordinary good reasons but because it cost them less. The problem was analogous with that of out-patients. In Kensington, patients were being referred through the M.O.H. back to the private practitioners, but a process of "Dutch auction"—general reduction of rates—was widespread.

Dr. Picken accepted the motion for the Council, and it was agreed. In moving the remainder of his report, however, he raised the subject at length in speaking of maternal mortality. The Association had, he said, recently carried out an investigation through private practitioners into the causes of maternal mortality, the only group of diseases against which a national public health campaign had proved unsuccessful. The Joint Midwifery Council had reported very rapidly, but had been able to use the results of much previous research. The Public Health Committee, in considering the report, had found itself in a difficulty. The Association's scheme was founded on continuity of treatment by the private practitioner, whereas the Joint Council had rather concentrated on the position of the midwife, the hub of its report being the need for a municipal midwifery service. The Association's Council had therefore appointed a special sub-committee to consider afresh the national maternity scheme of the Association with special reference to the Joint Council's report. He invited discussion by the meeting, so that if the Council of the Association had to take action before the next A.R.M. it might have some knowledge of what general practitioners felt.

Dr. A. Baldie (Kensington) claimed that Kensington was peculiarly entitled to an opinion, because its practitioners were surrounded by legitimately competing institutions. Over the whole country, however, the process went on of training doctors on the material they ought to be treating after they qualified—the profession manufactured and swallowed its own tail. Some arrangement should be made for institutions to charge a fee to women who could afford it. Efforts should be made to combat propaganda based on the alleged incompetence of general practitioners. The doctor was competent, though he might be out of practice through the incompetence of the community to provide him with opportunity. Midwifery should not be regarded as a specialty; childbirth was a physiological process and not a disease. Specialists should link up with general practitioners to formulate a scheme whereby the profession would not be faced with the fait accompli of a midwifery service run by laymen. No lay interference, political or otherwise, should be tolerated.

Dr. H. Guy Dain (chairman, Insurance Acts Committee) drew attention to the new prevalence of obstetric shock, and moved:—

> "That the B.M.A. regrets that the question of maternal mortality has become the subject of widespread political

---

[2] THE LANCET, 1935, i., 1507.

discussion, receiving great publicity in the lay press. Maternal mortality is a scientific and administrative problem which deserves careful and scientific study, but in the experience of practising doctors, the publicity which it is receiving to-day is tending to terrify child-bearing women and is, in itself, a cause of increased mortality."

This motion, seconded by Dr. A. BEAUCHAMP (Birmingham), was carried amid cheers.

Dr. A. B. MURRAY (Banff) claimed a mortality-rate in his district of one per thousand, and ascribed its lowness to a good general practitioner service. He feared that a service of whole-time midwives would lead to a service of whole-time doctors. A municipal service in his area would be prohibitively expensive.—Dr. KILLICK MILLARD (Leicester) declared that before the profession accepted the Joint Council's proposal, it should be satisfied that it represented the best solution.

Dr. H. H. MACWILLIAM (Liverpool) strongly supported the proposal for a salaried midwifery service. Liverpool midwives could not make an adequate income in private practice. He hoped they would be sent into suitable hospitals to enlarge their education, and to learn that "obstetric shock" was a refuge of the destitute and that such deaths were due to some other cause than fright induced by political propaganda.—Dr. C. F. SCOTT (Willesden) complained that Willesden borough council had built a maternity hospital five miles away, into which no doctor could follow his patient. Harrow, on the other hand, had opened a home into which general practitioners were invited, and paid them—instead of whole-time officers—if the patients could not. The patients much preferred being attended by their own doctors. —Dr. J. LIVINGSTONE (Barrow-in-Furness) deplored the practice of midwives in some areas of sending for certain doctors and not the patient's own attendant. This abuse should be brought to the attention of the Central Midwives Board, as relatives would not coöperate in local action.

Dr. J. MIDDLETON MARTIN (Gloucestershire) was astonished that the Joint Council should prefer a municipal service of midwives in view of the splendid clinical record of such bodies as the Queen Victoria's Jubilee Institute of Nurses. The best constructive suggestion so far was the scheme for antenatal examination by the practitioner who, at the request of the midwife, would attend the confinement. The more a midwife was encouraged to think of herself, the greater the likelihood of her interfering in a situation which needed the doctor.

Dr. D. O. TWINING (Plymouth) urged the claims of the rural district to a whole-time midwife. He did not like the district nurse to double the part, thinking that she would be a better nurse if she did not do midwifery and a safer midwife if she did not come to a confinement from other patients.—Dr. BEAUCHAMP suggested that midwives were often afraid to notify a temperature, but that a woman was as safe in her own home, attended by her own doctor, as anywhere. —SIR EWEN MACLEAN (Council) pointed out that of the women confined in England and Wales, about 65 per cent. were attended throughout by midwives and 10 per cent. went to hospital; this left a quarter —about 172,500—for the general practitioner. The standard of midwifery in the country must be set by the general practitioner. No scheme was possible which contemplated dividing the doctors of the country into those who might take part and those who might not. The base of an efficient system was a competent midwife. In many areas, a whole-time salaried service would be entirely inadvisable; in some nothing else would answer the purpose. The new sub-committee, the Council, and, next year, the Representative Body would have most carefully to consider the whole position.

Dr. W. PATERSON asked what the general practitioner thought of having large numbers of midwives as municipal officials. In answer to his invitation Dr. WATERFIELD championed the district nurse, whose knowledge of the people and hold on their confidence, were a great asset. The risk of infecting mothers from other sources was, he thought, very small. The patient should have some choice of midwife. As a practitioner, he preferred to be able to get his midwife assistant changed if necessary, and a local authority was much less approachable than a district nursing association.—Dr. W. G. THWAITES (Brighton) said that the usual patient who went wrong was a young married woman, who was physically unfit through tinned food, hard work, and indiscreet recreation. The Council should use these facts in combating political accusations of inefficiency.

Dr. W. G. WILLOUGHBY (Eastbourne) stated that the municipal home of which he had charge confined 35 per cent. of the mothers of the area, and the general practitioners often insisted on their patients going into it. Divisions should discuss this problem with their medical officers of health.—Dr. C. E. S. FLEMMING (Trowbridge) thought it did not matter whether the midwife was appointed by a municipality or a district committee, so long as she was competent. If the medical advisory committee was good, there should be no difficulty about approaching the local authority, who were often better able to choose a good nurse. The Queen's Nurses in Victoria, Australia, who handled cases of all kinds, showed a mortality-rate under 1 per 1000.—Dr. A. LYNDON (Guildford) supported the plea for a part-time midwife under an association. In his area the association sent its candidates to a small hospital for two years' training, and to a recognised school for their C.M.B. In his village there was a nurses' cottage with a good two-bed maternity ward. The nurses knew the whole circumstances of the patient, and the patient could select the nurse.

The motion to adopt the rest of the report was carried.

National Health Insurance

Dr. DAIN (chairman of the Insurance Acts Committee) moved his committee's report.

Dr. BALDIE (Kensington) moved that any scheme for supplementing general practitioner's service for insured persons by expert treatment and laboratory service should be initiated and administered in collaboration with the representatives of insurance practitioners. He stressed the need for auxiliary services such as radiological and pathological examination. He prophesied the necessity for modifying the dual control over insurance practice, and urged panel practitioners to put forward their own scheme in good time, to anticipate control by laymen and medical experts. Panel representatives would assert the principle of medical control of all services, administrative and clinical.—Dr. DAIN warmly approved the principle of the motion, and it was carried unanimously.

Dr. J. C. ARTHUR (Gateshead) opposed the Council's suggestion, at a time marked by encroachment of all kinds, to set up a clinic to diagnose and treat anæmia. A general practitioner could estimate hæmoglobin in a few minutes and test whole blood in a quarter of an hour. He deprecated what he called a declaration of the general practitioner's incompetence. Nevertheless, the meeting accepted the committee's report without dissent.

Tunbridge Wells, through Dr. B. H. Pain, moved a motion desiring the abolition of the compulsory statistical compilation of national health insurance cards, and asking that such cards be used *primarily* for clinical notes. He asked for voluntary record-keeping, more clinical and less statistical, and for requests for accurate records on some one disease, to be sent to the Medical Research Council. Panel doctors would then feel themselves fellow-workers with the greatest research students. The Ministry must now possess all the statistics they needed.—Dr. Howie Wood (Isle of Wight), in support, compared the relationship between the panel doctor and the regional medical officer with that of a stern schoolmaster and a recalcitrant pupil. In his area the practitioners prided themselves on putting down all possible clinical data, but did not meticulously note every attendance. They, however, had a reasonable R.M.O.—Dr. Flemming said the real objection to recording the number of attendances was that the Ministry regarded these figures as a measure of the value of the practitioner's work.

Dr. A. B. Murray boasted that this reform had been accomplished in Scotland five years before. The Scottish Board of Health had replaced the records by a return of patients needing admission to hospital, and then by clinical returns—e.g., on early signs of cardiac and valvular disease. It was hoped that a more elastic scheme would be provided, allowing the doctor to record matters which chiefly interested him. His scientific work was more valuable than the collection of statistics.

Dr. Dain replied that panel doctors already kept clinical records, the quality of which was improving. The Ministry were agreeing to lay less stress on the statistical side. He did not find the marking of the cards any burden, as some colleagues seemed to find it. Those who kept these records well were more likely to keep good clinical ones than those who resented doing so. He hoped that the Representative Body would not express an opinion on a business matter concerning only panel practitioners and the Ministry.

Sir Henry Brackenbury, while expressing himself as in favour of the motion, agreed that the matter should be left to the Panel Conference. His opinion that a divergence of opinion between the two conferences would be a lamentable thing was shared by a large majority, and the meeting forthwith passed to the next business.

Consultants and Specialists

Prof. A. H. Burgess (chairman of the Consultants' and Specialists' Group Committee for England and Wales), moving a recommendation that domiciliary attendance by a consultant should, when possible, be provided by a consultant in private practice, explained that a certain county council had advertised for whole-time salaried staff for their hospital, on condition that successful candidates must act as consultants to general medical practitioners outside if called on, the fee to go to the council. This council proposed to make the services of its obstetric consultants available to some of its local authorities for maternity and child welfare work. The recommendation would not affect consultations on notifiable diseases. The Council of the B.M.A. would, if the meeting accepted the resolution, request divisions and branches to enact ethical rules in the same sense. This was carried unanimously by vote, and became the policy of the Association.

Prof. Burgess, proposing the adoption of the remainder of this report, said that his Committee were in favour of the principle of extending National Health Insurance under suitable conditions. He also proposed:—

> "That it is in the general interest of the public and of medicine that consultant members of staffs of council hospitals should, as a rule, be part-time and not whole-time officers."

He pointed out that the part-time officer had the stimulus of consultation with the general practitioner, and sometimes of association with students; he was also available for the public and allowed greater freedom of choice of doctor and absence of red tape.

Dr. H. Robinson (Kensington) moved to refer this back to Council, on the ground that it was based on conditions obsolete since 1929, and supported his contention with many instances. The policy of the Association, he said, must not only be in the public interests, but must also appear to be so; he feared that the proposed resolution would arouse the opposition of the public and of the L.C.C. He received the support of Dr. E. W. G. Masterman (*Council*), who regarded the motion as very dangerous. He was most anxious that municipal hospital officers in charge of severe cases and instructing students—as they now did in many hospitals—should be specially qualified for their work. The resolution might block this desirable procedure. The authority of Sir Henry Brackenbury, however, was thrown into the scale on behalf of the motion which, he admitted frankly, was a general rule with very many exceptions. London was unique, and its Council was tackling its vast job extraordinarily well; nevertheless it should not govern the rule for the whole country. The rules had been formulated in 1930, because of the 1929 Act, and did not antedate it as Dr. Robinson had suggested. If a large number of counties appointed whole-time consultants with liberty to act as private consultants throughout the area, private consultant practice would not be worth having in the future. One large county had already adopted that method, and if the Association could, it had to stop it at the beginning.

The Chairman of the Council emphasised the warning against taking London as a standard, and assured the meeting that the matter had been debated again and again in Council, and reference back could lead to no different result.

Dr. M. W. Renton (Dartford) pleaded for consideration of the part-time general practitioner, to whom far more scope should be given on the staffs of these hospitals. He argued that he was in order in mentioning general practitioners, because the interests of the consultants were identical with theirs and evoked applause by his commendation of their work on these hospitals. Consultants must not be cloistered, declared Mr. Bishop Harman, returning to the point, and urged the meeting to reinforce the view that the best consultant was he who worked both in hospitals and in private. Dr. Robinson was not dismayed by the forces ranged against him, but failed to carry more than a few of the members with him.

West London Hospital.—Princess Arthur of Connaught visited this hospital on "pound day" to receive the gifts from visitors. Nearly a thousand school children were present to make their contributions. It is hoped before the end of the year to complete *the* new buildings, which will be known as the "Silver Jubilee extensions."

THE OSTEOPATHS BILL

REPORT FROM THE SELECT COMMITTEE

ON April 12th the sittings of the Select Committee of the House of Lords appointed to consider the Registration and Regulation of Osteopaths Bill were abruptly terminated, the supporters of the Bill having withdrawn their support, before all the witnesses against it had been heard. The Committee, which consisted of Lord Amulree (chairman), Lord Dawson of Penn, Lord Elibank, Lord Esher, Lord Carnock, Lord Marley, and Lord Redesdale, have now issued a unanimous report which is set out below.

1. The Committee have occupied twelve days in their inquiry, in the course of which they have examined twenty witnesses. Before the evidence of those opposing the Bill had been concluded the supporters of the Bill intimated that they did not desire to ask the Committee to recommend that it should be proceeded with.[1] The Committee, however, conceived it to be nevertheless their duty to report in detail to the House.

2. The principal object of the Bill was stated to be the protection of the public against the practice of osteopathy by incompetent or unqualified persons. Learned counsel, in opening the case for the Bill, put it to the Committee that it would be sufficient for him to establish (*a*) that osteopathy is extensively practised, and (*b*) that the public in large and increasing numbers are desirous of being treated by this method. On these hypotheses he asked the Committee to deduce that Parliament should authorise the establishment of a state register for osteopaths, with a prescribed qualifying education and standard of proficiency; in fact, to accept the Bill in principle.

3. In all comparable cases of vocations for which a statutory register has been authorised, three conditions have been fulfilled, viz. :—

(i) The sphere or territory within which the vocation operates has been clearly defined.

(ii) The vocation has already long been in general use.

(iii) There has been already in existence a well-established and efficient system of voluntary examination and registration.

The establishment of a state register moreover not merely protects the public from the unqualified practitioner, but gives the guarantee of Parliament that persons of the class proposed to be registered are within their own sphere worthy, and the only persons worthy, of the public confidence. Instances (besides the medical register) are the registers of dentists, pharmacists, midwives and veterinary surgeons. The province of each can be clearly defined, the practice of each is universal, and each was in a state of efficient voluntary organisation at the time when the statutory register was established.

4. In the case of the osteopathic calling none of these conditions can be said to be fulfilled, for the following reasons :—

(i) No definition of osteopathy was included in the Bill as introduced, and although one was subsequently proposed for inclusion in the Bill, and others suggested, none emerged which satisfactorily differentiated the osteopathic sphere of activity.

(ii) The practice of osteopathy, though widespread in the United States of America and Canada, is carried on in the United Kingdom by not more than two to three thousand practitioners, of whom only about 170 can claim to be "qualified." It is practically unknown on the continent of Europe.

(iii) The only existing establishment in this country for the education and examination of osteopaths was exposed, in the course of evidence before us, as being of negligible importance, inefficient for its purpose, and above all in thoroughly dishonest hands. Pending the setting up of any adequate machinery in this country, therefore, the only training ground for the qualified osteopath would be North America, and it was pointed out by the representative of the Ministry of Health that "it is alien to the general principles which have so far been followed in comparable legislation to recognise qualifications which are conferred by foreign educational institutions." Moreover the Committee had no evidence before them as to the standard of education of osteopaths in North America.

5. In view of the fact that the establishment of a statutory register would give something in the nature of a "hall-mark" to osteopathy, the Committee felt it their duty to inquire at some length into the nature and value of osteopathic treatment. It emerged clearly that osteopathy is not—as is popularly supposed—a craft or art limited to the treatment of maladies or defects of the bones, joints, muscles, ligaments, &c., by manipulation; in this sphere the Committee have no doubt that qualified osteopaths perform valuable services. They may even possibly be regarded as having at one time developed a technique in advance of medical science, which has been to some extent accepted by members of the medical profession who practise what is called "manipulative surgery". Osteopathy, however, claims to be a method of healing which is suitable for the treatment of *all diseases of any description*. "We claim," said Dr. Streeter in evidence, "we have a different school of healing, and we want provision made for it, and an orthodox curriculum. We want to develop along our own lines; we feel we are just as competent as any physician to act as a family physician and general practitioner."

6. As the law stands, anyone is entitled to practise the art of healing, but only registered medical practitioners are entitled to hold themselves out as duly qualified to treat all diseases. Were the present Bill to pass, registered osteopaths would be entitled to make a like claim. It is true that, on no logical principle, provisions were proposed for insertion in the Bill, excluding osteopaths from the right to perform "major surgery", to practise midwifery, to administer anæsthetics and to give certificates of the cause of death; but neither of the distinguished practising osteopaths, who gave evidence before us, would recede in any way from the full claim of osteopathy to treat all disease.

7. It is hardly necessary to point out the far-reaching nature of this claim, involving as it does the statutory recognition of two alternative, and to a great extent conflicting, theories of healing. Dr. Kelman Macdonald explained his views as to the scientific basis upon which the osteopathic theory reposes, and the Committee would wish to pay a tribute to the ability and sincerity of this witness; but Dr. Macdonald is actually a registered medical practitioner, and, whilst he clung to the formulæ on which osteopathy is based, it was clear that in actual practice he would not deny his patients, where

---

[1] The reasons given by the supporters of the Bill were as follows :—

(*a*) That they desired what they considered to be the scientific basis of osteopathy to be further explored.

(*b*) That they could not properly ask for a measure which required for its full operation the granting of powers to the British School of Osteopathy, the present constitution of which the principal supporters did not approve.

necessary, the benefit of appropriate medical or surgical treatment.[2]

8. The Committee accept the claim that cures are frequently effected by osteopathic methods. On the other hand there have been some failures. The same may be said of other methods of healing. The Committee have not been in any considerable degree influenced by evidence either of cures or of failures.

9. The Committee find on the evidence before them that the claim of the osteopaths to be able to treat all diseases as set out in the Bill has not been established, and that it would not be safe or proper for Parliament to recognise osteopathic practitioners as qualified, on a similar footing to that of registered medical practitioners, to diagnose and treat all human complaints.

10. Further, the Committee are of opinion that the question of establishing a register of qualified osteopaths by Act of Parliament should in any case be deferred until the sphere of osteopathy has been defined, and a system of education in the principles and practice of osteopathy has been developed in this country in one or more well equipped and properly conducted institutions.

11. A question was raised in the course of the hearing as to whether there should be what was described as a "scientific" inquiry into the merits of the principles and practice of osteopathy. The president of the General Medical Council said he had no objection to such an inquiry. The Ministry of Health considered that before any register was authorised by statute the theory and practice of osteopathy should be established by such an inquiry. As already stated, the Committee have reached the conclusion that the claim of the osteopaths to be able to treat all diseases has not been established and they are satisfied that such conclusion is sound.

12. The Committee, in view of the considerations set out above, have ordered that the Bill be reported to the House without amendment, and recommend that it be not further proceeded with.

MEDICINE AND THE LAW

Damages for Slippery Floors

IN Weigall *v.* Westminster Hospital, Mr. Justice Horridge, last week, awarded the substantial sum of £2826 to a plaintiff who broke her thigh by slipping on a polished floor at the hospital's annexe at Hampstead. Mrs. Weigall, the plaintiff, was visiting her son who was a paying patient at the hospital. While inside the building she went to see the consulting surgeon. The floor of the room was covered with highly polished linoleum; near the fireplace was a mat which suddenly slipped when she put her foot upon it. She fell on her side and broke her left thigh; in consequence, her left leg is now an inch shorter than the right. It was negligent of the defendant hospital, she contended, to put a mat on a slippery floor without taking proper steps to ensure that it would be stable when trodden on. The defendants denied negligence and suggested that the fall was a mere accident caused by Mrs. Weigall losing her balance on suddenly turning round to speak to the surgeon. There was also apparently, at one stage of the case, an argument that there was not the same duty to the plaintiff if she went to see members of the staff in their rooms as when she merely went to see a patient. The judge found for the plaintiff all along the line. He accepted her account of the cause of the fall. He said there was an implied contract that she should be at liberty to visit her son, and also that she should be at liberty to consult the surgeon with regard to her son's condition. That was the normal course of events when she visited her son. She was present on the hospital's premises as an invitee. The judge cited and followed a decision of Lord Hailsham to the effect that, where persons are present by the invitation of the occupier, there is a duty upon the occupier to take reasonable care that the premises are safe. In Mrs. Weigall's case the court was satisfied that there had not been reasonable care. The defendants could not say they were unaware that the floor was highly polished; indeed the secretary of the hospital had said that it was kept polished for antiseptic purposes. If mats were placed on such a floor, there was a duty to take some precautions to prevent them slipping. The defendants ought to have known that the mat might slip, and the plaintiff was not to know that no precautions had been taken to prevent it slipping. Mrs. Weigall had not been guilty of any contributory negligence; it was not for her to take care to see that the defendants had secured the mat before she put her foot on it.

The slippery mat on the highly polished floor at the hospital—which his Lordship found to be an "unusual danger" within the knowledge of the hospital—would equally be taken to be a want of reasonable care if it led to accident inside the house of a surgeon or physician. The case of Weigall *v.* Westminster Hospital is a warning. The hospitals indeed, have been warned already. A year ago an elderly patient in a Yorkshire hospital, getting out of bed in the absence of the nurse, slipped on the polished floor and sustained injuries which accelerated his death. The coroner[1] commented on the danger of polishing the floor of a ward where elderly and infirm patients were accommodated, especially if the patients wore leather-soled slippers. A year earlier[2] the question of suitable hospital flooring was discussed in our columns in connexion with a report on hospital construction, compiled by an international congress. A floor covering should be both silent and safe, and, as we then ventured to say, the surface should not be one which by any process known to woman can be polished. We were thinking of the safety of house surgeons and nurses as well as that of patients. Mrs. Weigall's successful claim is a reminder that visitors also have to be considered and that their accidents, unless covered by insurance, may have a disturbing effect on hospital finance.

Obstructing a Coroner

It is a criminal offence to dispose of a dead body so as to prevent a coroner from holding an inquest. The offence varies greatly in seriousness. It can be aggravated by suspicions of murder, or, as appears from the following case at the Old Bailey last week, it can be a trivial matter meriting no grave punishment. An old man named Ellis disappeared on July 5th, 1934. About a year later his body was found in the cellar of a public-house in the Blackfriars-road. On the day of his disappearance he had visited the public-house and had fallen through the trapdoor of the cellar (which ought not to have been left open) and had thus met his death. The barman of the public-house, possibly afraid of being scolded for not having closed the trapdoor, disposed of the body by hiding it in the cellar. There was this to be said for the barman—he had just had to give evidence about another accidental death at the public-house and, being perhaps of a more sensitive nature than others who follow the same calling, he had flinched from repeating the experience of being a witness at a second inquest. The medical evidence established that Ellis's death was due to the accidental fall through the trapdoor; there was no suggestion of foul play. When Ellis's body was at length discovered, the barman made a full and frank statement which the police were able to accept as true. He was indicted for unlawfully disposing of Ellis's body with intent to prevent a coroner's inquest, when such inquest ought to have been held. He pleaded "guilty" and received the nominal sentence of three days' imprisonment, which, in the circumstances, meant that he was forthwith released from custody.

---

[2] On the other hand, in answer to a question whether the Bill would "provide a bridge over which one will be able to pass and meet the other in the middle," he answered, "I think so, but on the other hand, you must remember that our views on the actual causation of disease, and our general guiding principles, and our form of treatment are all at complete variance with those of the medical school."

[1] THE LANCET, 1934, i., 1376.

[2] Ibid., 1933, ii., 392.

The particular offence with which the barman was charged is not committed unless an inquest ought to have been held on the body. This point was brought out in R. *v.* Purcy,[3] where members of a homeless family left in a hedge the body of a child. The child had been ailing and ill-nourished, but there was nothing to indicate that the death had been due to criminal negligence. The death would consequently not have been one for investigation by the coroner. In the Court of Criminal Appeal the Lord Chief Justice seemed to hold that the Purcy family had not committed the crime with which they were charged, because an inquest would not necessarily have been held. In the recent case of the barman, an inquest would presumably have been held upon the death of Ellis who fell through the trapdoor, but it looks as though the barman had an excellent defence. The Recorder accepted the statement that the barman had no real intention of committing any offence. An unlawful intention to prevent the inquest was, however, an indispensable ingredient of the crime. If the barman had no such intention—if, for instance, he hid the body to escape being scolded about the trapdoor—he was entitled to be acquitted, and he need not have pleaded "guilty."

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

THE OUTLOOK FOR NEW MEDICAL GRADUATES

NEARLY 200 degrees were conferred at the medical graduation at Edinburgh University last week, and Prof. R. W. Johnstone, F.C.O.G., in his address as promotor, was able to provide some interesting information and comments on the prospects of professional success at the present day.

The State, having made itself partly responsible for the health of the people, is, he said, finding itself more and more deeply committed, and future extension of the National Health Insurance Acts will probably lead to 90 per cent. of the population of the country being either "on the panel" or under public assistance schemes. The field of private practice is likely, therefore, to become greatly restricted, but as an offset to this there will be a considerable and probably disproportionate increase in the number of salaried appointments. The position of the voluntary hospitals will inevitably be effected; the change is already in process, and the outcome is a matter of deep concern. The present system of providing free medical attention and accommodation for those who are in no real sense in the category of the necessitous poor must call for revision.

In success or failure, Prof. Johnstone said, character and personality counted for more than intellectual ability and still more than mere knowledge. He went on to give the results of his investigations concerning the degree of professional success achieved by the 1766 men and women who graduated as bachelors of medicine and surgery at Edinburgh from 1900 to 1909. Of these, 53 were killed or died in the War, and 268 have dropped out of the live roll, mainly by death; the Medical Directory still contains 1445 of the 1766 names. From his analysis Prof. Johnstone estimates that just under 3 per cent. have achieved distinguished success, 31 per cent. considerable success, and 55 per cent. a fair degree of success. There remain 11 per cent. who cannot be traced, many of whom are probably failures. One-third of the total, therefore, have achieved more than just a moderate degree of professional success. Eighty per cent. have entered general practice, and only 30 per cent. have taken the degree of M.D. One or more of the higher diplomas have been taken by 26 per cent. and the fellowship of one or other of the Royal Colleges by 16 per cent. One man is an F.R.S., 38 have become professors, and 68 are lecturers in universities of the Empire or in America. Fifty-five are on the staffs of teaching hospitals, and double that number on the staffs of large non-teaching hospitals in Great Britain. A total of 62 have become medical officers of health of large cities or counties, and 30 are superintendents of asylums. The regular Imperial Services have absorbed 192, two-thirds of them in the Army Medical Services. Of 100 women on the list, 60 have married.

The promotor pointed out that there is an impending glut in the medical market, but he did not think there was any occasion for alarm, since the supply was likely to adjust itself to the demand. In conclusion he said that the doctor whose aim is simply to do as much good to his patients and fellow men as he can, may thereby gain a serenity of mind which will make his life a complete and rounded success, quite independently of such matters as professional distinction and financial prosperity.

VIENNA

(FROM OUR OWN CORRESPONDENT)

THE NEW DISPENSATION IN MEDICINE

THE Government has long promised fresh legislation on health insurance and old age pensions as part of its reorganisation programme. Particulars of the new law were not made public in advance, for the present "autocratic" system of government has done away with parliamentary institutions, and the federal council can do no more than accept or reject the Bills presented to them by the government or ministries. It is even likely that the representatives of the medical profession sitting on this council (who were elected as well as nominated by the government) were neither asked nor allowed to express their opinion. The law came into force on July 1st after a transition period of three months. During this period, which was designed to familiarise the public and the authorities with the new system, the changes actually effected were very slight; passive resistance appeared to be widespread. The perpetrators of the law (if this expression may be used) evidently realised that it was not an ideal solution, for they have limited its working to a trial period of five years.

---

[3] Ibid., 1933, i., 1035.

As soon as the law was published it was criticised and opposed, both by the medical profession and by the insured persons. In medical journals of differing standpoints it was emphasised that the results would be ruinous to the medical profession unless radical changes were soon introduced, and the justification of such complaints will soon be apparent. The chief aim of the new scheme seems to be economy in social expenditure; benefits for the insured persons and medical salaries are alike to be cut down. Allowances for medical treatment, accommodation in hospitals, benefits during sickness and convalescence and old age pensions have all been severely "axed," sometimes by as much as 40 per cent., and the effect on public health is bound to be unfavourable. Not only are the benefits of insured persons to be reduced, but sickness insurance is henceforth to be limited to the wife (or husband) of the wage-earner and to children under eighteen years of age. Old age pensions are being reduced by 25–40 per cent., and will be paid at sixty-five instead of sixty. The maximum payment, which is made to members with forty years' subscriptions, will be 280 Austrian schilling (£10 15*s.*) a month instead of 400 schilling.

The following regulations will affect the medical profession. Under the auspices of a central union called the Federal League of Social Insurance (Der Reichsverband der Social-Versicherungs-Träger) there will be a committee (Arbeitsgemeinschaft) in each county, corresponding to the present Krankenkasse or sick club. This will supply medical and dental aid, allot sick pay, and make financial arrangements with doctors, dispensaries, and other institutions. A special medical committee will deal with the appointment of doctors, and in coöperation with the main committee will settle any differences of opinion which may arise in the administration of the new regulations. The medical committee will consist of an equal number of representatives of the local medical organisation and the general insurance committee, but the chairman will be a layman, preferably a high official of the federal civil service appointed by the local government. Insured persons may choose their doctor or dentist from a panel of approved practitioners, admission to which is open only to Austrian citizens with a medical degree from an Austrian university. Insurance doctors must have done at least four years' medical work, including at least three years in a public hospital or sanatorium; they must have experience of surgery, obstetrics, and internal medicine, and have acted as locum tenents to a general practitioner for at least three months. Consultants must have had 4–5 years' training in their specialty in a recognised hospital; and dentists must have spent two years in a dental department and two years in private practice.

A candidate for admission to the panel must satisfy the authorities of his good citizenship and blameless professional behaviour. A novel feature is the condition that no doctor may be appointed to this list if he draws a fixed income of 12,000 schilling (£480) a year from other permanent medical employments or from other public sources. Nobody in the new State may derive a double income from public funds; but specialists are exempt from this condition. Even if the candidate has fulfilled all these requirements his admission to the panel service under the social insurance law is at the discretion of the medical committee, and it has been pointed out repeatedly in medical journals that this "discretion" is a very severe test of the impartiality of members of the committee. Not only may racial, religious, political and economic factors influence their decision, but also personal likes and dislikes.

Formerly a panel appointment carried with it either a fixed income for the sick-club doctor, or a sliding income per head. Now a fixed percentage of the income of each county committee will be devoted to the payment of the doctors on its panel, and this sum will have to cover all expenditure for medical aid. The services of the doctors will be paid according to a system of "points." Every visit, operation, consultation, or dressing will represent so many points, and the doctor's monthly salary will be decided by the number accumulated. The value of the point will fluctuate according to the amount of money available. But the point value for the workmen's Krankenkasse may be different from that in the employee's Krankenkasse, and the point value may (and most likely will) vary from year to year. The medical committee is entitled to discard this system, and in any suitable case establish instead for the benefit of an individual doctor a fixed salary. This may be done in any district or part of a district for special reasons which are again left to the discretion of the committee. Thus we find again those opportunities for differentiation, discrimination, and arbitrary decisions among the panel doctors which have already been bitterly criticised in the medical press.

The main object of the new law is admittedly to save expense, and it is certain that a number of doctors will be gradually dismissed from the Krankenkasse. The following regulations have been drawn up for such dismissals: a practitioner with less than ten years' service may be dismissed within one year after the new law comes into force. He is, however, entitled to compensation depending on the length of his service, the maximum being one year's salary. If he is later readmitted to the panel, he must refund this sum in monthly instalments. A practitioner with more than ten years' service has hitherto been entitled to a pension. All previous agreements to the effect that a panel physician may not be dismissed except by reason of gross default are declared invalid, and a pensioned physician who is readmitted to the service under the new law receives no pension during the time of his service. The administration of these rules is also in the hands of the medical committee, and the doctor has no right of appeal.

These brief notes on the new law are proof enough of its spirit and contents. They show the great power of the committees and the defenceless position into which the profession has been manœuvred. This impression is intensified by the fact that under the new law there is no longer the hope of a pension after prolonged service. The chief advantage which the new regulations bring is the abolition of all fixed salaries, and that, nominally at least, the chances are now the same for all. Another advantage is that the patients may choose the doctor they have most confidence in. But on the other hand, the doctor may only prescribe approved remedies, and will have to give up many medicines to which he has become accustomed, for the list of drugs has also been cut down. Taking it all in all we see that our profession is hampered, its expectation of a decent payment for its work are nullified, and the doctors themselves are threatened by proletarisation since private practice is dwindling away. Indeed, as several medical journals emphasise, the necessity for alterations in the law, even before the lapse of five years, is obvious, for although the "transition" period of three months has passed without radical changes in the staff of the existing sick-clubs many doctors fear the coming autumn. And a man who loses his post in the panel service will hardly be able to find a living elsewhere.

CORRESPONDENCE

THE SMITH-PETERSEN NAIL

To the Editor of THE LANCET

SIR,—The directing apparatus for the insertion of Smith-Petersen nails, described by Mr. Eric Lloyd in your last issue, shows great ingenuity; complicated as it may be he has succeeded in greatly simplifying the apparatus of Sven Johannsen. Nevertheless, from experience with other types of directing apparatus one is driven to the conclusion that this is yet another instrument subject to instrumental error which introduces unnecessary complications and difficulties into the technique of insertion of the nail.

There is only one drawback to the use of Smith-Petersen's nail for fractures of the neck of the femur. Unless the nail enters exactly into the centre of the proximal fragment there is a danger of refracture of the head of the femur with redisplacement. While it is true that Mr. Lloyd's apparatus by controlling alignment in two directions aims at accurate centralisation of the nail, one feels that the calculation of small angles on wet films, and the setting of an instrument of this type must at some time or another lead to sufficient error to allow a nail to lie somewhat eccentrically. In such a case even although its alignment is perfect the sector of bone holding the nail in the head will be too small to overcome the danger of refracture.

Not only does one feel that such an apparatus may possibly lead to error, but the technique which I have developed for the insertion of the nail over a guide through an open incision has now become a matter of the greatest simplicity. It is an operation associated with very little shock and with the loss of only an ounce or two of blood; it can be completed in thirty to forty minutes, and I have now performed it in fifty cases including a high proportion of patients of 70 to 80 years of age suffering from chronic bronchitis, auricular fibrillation, prostatic enlargement, uræmia, pernicious anæmia and all of the diseases of old age, with a mortality of only 6 per cent. which is much lower than one used to accept as inevitable whatever treatment was adopted.

Some years ago one felt that a true subcutaneous insertion might be of value in a group of patients who could not withstand the shock of an ordinary operation, and Mr. Lloyd's suggestion falls very much closer to this ideal than the Svan Johannsen operation, which in fact is not a subcutaneous procedure at all. With the improvement in the technique of the open operation, however, I begin to doubt whether there is any scope for the subcutaneous insertion. In the last four years I have operated on 40 of the 46 cases I have seen; the remaining six cases were aged 80 to 92, and I feel that even a subcutaneous insertion would have proved too much for them.

One feels therefore that a blind instrumental insertion with its risk of imperfect and inaccurate centring and the delays and difficulties of X ray control in the operating theatre cannot compare with the 30-minute operation associated with so low a mortality in such an unpromising group of patients.

I am, Sir, yours faithfully,

Liverpool, July 22nd. R. WATSON JONES.

ARTIFICIAL RESPIRATION

To the Editor of THE LANCET

SIR,—Dr. Mijnlieff's article in your last issue, in which the Schäfer method of artificial respiration is depreciated, is one with which I believe that nearly all competent British and American authorities will disagree.

I have been a member of nearly all of the commissions and committees in America that have studied and reported on this subject during the past quarter of a century, and have been in close touch with the application and results of their investigations and reports. All have recommended the Schäfer method above all others for general use. How completely American opinion, supported by an enormous experience, is unanimous in support of the Schäfer method is indicated by the fact that more than 13,000,000 persons—police, firemen, coastguards, boy and girl scouts, school and college students and others—have been trained to administer this method, and no other is taught to them.

The advantages of the Schäfer method are indeed particularly great for the operator, both for immediate application and for prolonged maintainance. For the victim no method of manual artificial respiration can do more than to induce rhythmic expirations. This is true, as I know from my own investigations and experience, no matter how much the writers whom Dr. Mijnlieff quotes may claim the contrary. Active respiration cannot be induced by any form of manual manipulation. The inspirations that occur between the forced expirations are due solely to the tonic elasticity of the victim's own muscles—a topic that I have discussed in a paper appearing elsewhere (p. 178). In that respect the Schäfer method does at least as much as any other manual method if the arms of the victim are drawn forward and placed so that the head rests on one forearm.

For these reasons I beg to differ from the statement in your editorial that "Dr. Mijnlieff is able to make out a good case for preferring it [the Silvester method] to that of Schäfer."

The one method that may, perhaps, prove to have some advantages over Schäfer's is that recently described by Eve.[1] But as that method requires at least an extemporised see-saw, it falls perhaps somewhat outside of the topic of manual artificial respiration.

I am, Sir, yours faithfully,

London, July 20th. YANDELL HENDERSON.

VIRUS BODIES IN THE PERICARDIAL FLUID OF RHEUMATIC FEVER

To the Editor of THE LANCET

SIR,—The problem of the cause of rheumatic fever, reanimated in this country by the recent work on virus bodies is, we must all agree, of international importance. I think that in advancing any such study, the various views should be expressed, although in the spirit of progress and not of antagonism.

Dr. A. E. Coles, in your last issue, has added to the literature of the virus bodies in the pericardial fluid of rheumatic fever, and in his comment writes as follows: "From a clinical and pathological aspect both these diseases are more closely associated with a virus than a bacterial origin." He is alluding to rheumatic fever and rheumatoid arthritis.

This is one of those general statements easily accepted by many, and also important. Accordingly, having for many years at first hand studied the clinical and pathological aspects of acute rheumatism in childhood I venture to write this sentence: Acute rheumatism in childhood shows clinically and pathologically *its close association* with a bacterial origin. This does not exclude the possible importance of a virus. It may be—I do not know—that these virus bodies mark a further step in our knowledge of all infective processes, but that both clinically and pathologically acute rheumatism in childhood shows the *closest possible* association with a bacterial origin I have not the slightest doubt, and, further, continental and American investigators are numerous who would support this statement.

I am, Sir, yours faithfully,

July 20th. F. JOHN POYNTON.

THE MEDICAL DIRECTORY

To the Editor of THE LANCET

SIR,—To maintain the accuracy of our annual volume we rely upon the return of our schedule, which has been posted to each member of the medical profession. Should the schedule have been lost or mislaid we will gladly forward a duplicate upon request. The full names of the doctor should be sent for identification.

We are, Sir, yours faithfully,

J. and A. CHURCHILL, LTD.

40, Gloucester-place, Portman-square, London, W., July 15th.

BLEEDING OF TRANSFUSION DONORS

To the Editor of THE LANCET

SIR,—Dr. Shackle writes two days after the publication of our paper practically dismissing our method as unnecessary or useless. He has not thought it worth while fairly to try out the technique *as described* before rushing into print to condemn it. We would not have deemed this hasty criticism worthy of reply were it not for the fact that this is the second time we have suffered attack from Dr. Shackle in this way. In your issue of April 27th we published an article on "Continuous Drip Blood Transfusion." This also evoked from Dr. Shackle a letter of disparagement. On that occasion we forebore to reply hoping that readers would note Dr. Shackle's admission in his opening paragraph that he had no experience of what he criticised and find in it a measure for evaluating his observations. In his two letters he has found no single good word for either of our contributions. We would suggest to him that to publish destructive criticism of new methods without trial of them is as unfair as it is misleading. Criticism after reasonable test is legitimate and welcome.

We do not propose to meet Dr. Shackle's individua assertions with counter assertions: We would prefe to ask less biased readers to try the method fo themselves and then to judge our claims and Dr Shackle's criticisms. They will not achieve anything so astounding as "a stream of blood the size of a ordinary lead pencil," which Dr. Shackle obtains from a serum needle, and which seems to be a true instance of "yielding more blood than its lumen will carry." They will find, however, we think, that as a rule they can obtain a pint of blood inside five minutes with ease.

We are, Sir, yours faithfully,

H. L. MARRIOTT,
H. KEKWICK.

The Middlesex Hospital, London, W., July 21st.

THE SERVICES

ROYAL NAVAL MEDICAL SERVICE

M.O.'S AND CIVIL HOSPITALS

By Order in Council of August 11th, 1903, candidates for commissions as medical officers in the Navy who, at the time of passing the qualifying examination for admission, hold or are about to hold posts as resident medical or surgical officer in a recognised civil hospital, may be allowed to serve in these appointments after the date of entry into the Royal Navy. By an Order in Council published in the *London Gazette* of July 19th, 1935, this provision is made applicable to candidates who enter the Naval Medical Service as surgeon lieutenants for short service. The time spent in the civil hospital appointment is to count for purposes of seniority, pay and promotion. and retired pay or gratuity on retirement, in the manner prescribed in the Order in Council dated June 29th, 1934.

Surg. Capts. E. Moxon-Browne to *Victory* for R. N.B.; and J. G. Danson to *Pembroke* for R.N. Hospl., Chatham.

Surg. Cmdrs. J. C. Brown to *Royal Sovereign* and to *Barham*; L. F. Strugnell to *Royal Sovereign*; J. Kirker to *Victory* for R.M. Infirmary, Portsmouth; H. E. Scargill to *Iron Duke*; A. de B. Joyce to *Victory* for R.N.B., and to *Excellent*; F. G. Hunt to *Glorious*; G. E. Heath to *Courageous*; and J. C. Kelly, D.S.C., to *President* for course.

Surg. Lt.-Comdrs. E. R. Sorley to *Victory* for R.N.B.; and J. Cussen to *President* for R.A.F. Medical Officers course; F. G. V. Scovell to *Pembroke* for Chatham Dockyard; F C. M. Bamford to *Pembroke* for R.N.B.; J. M. Sloane to *Drake* for R.N.B.; J. J. Keevil to *Victory* for Haslar Hospl.; W. R. S. Panckridge to *Nelson*; and A. D. Sinclair to *Cormorant* for Gibraltar Dockyard.

Surg. Lt.-Comdr. (D) T. Hunt to *St. Vincent*.

Surg. Lts. J. M. Holford to *Valiant*; and S. C. S. Cooke to *Deptford* on commg.; B. R. Alderson to *Glorious*; D. C. Robson to *Bridgewater*; S. J. van Pelt to *Royal Sovereign* and to *Barham*; M. Cay to *Royal Sovereign*; and E. B. Bradbury to *Endeavour*.

Surg. Lts. (D) F R. McN. Willis to *Drake* for R.N.B.; W. L. Mountain to *Royal Sovereign*; W. H. Foy to *Pembroke* for R.N. Hospl.; and E. F. St. J. Lyburn dna D. Simpson to *Australia*.

The following promotions have been made: Surg. Lt. E. H. Parkinson to be Surg. Lt.-Comdr.; Surg. Lt. (D) R. Symmons to be Surg. Lt.-Comdr. (D); and Proby. Surg. Sub.-Lt. K. E. O. Ringdahl to be Surg. Sub.-Lt.

ROYAL NAVAL VOLUNTEER RESERVE

Surg. Lt. (D) R. Symmons to be Surg. Lt.-Comdr (*D*).

Surg. Lt. E. H. Parkinson to be Surg. Lt.-Comdr.

Proby. Surg Sub-Lt. K. E. O. Ringdahl to be Surg. Sub-Lt.

Surg. Lt.-Comdr. J. D. Simpson to *Excellent*.

Surg. Lt. D. R. Goodfellow transferred from *list* 1 to list 2 of the Mersey Div.

Surg. Sub-Lt. D. Shute promoted to Surg. Lt.

ROYAL ARMY MEDICAL CORPS

Short Serv. Commissions.—Lt. W. T. Bermingham to be Capt.

L. C. Card to be Lt. (on prob.).

REGULAR ARMY RESERVE OF OFFICERS

The undermentioned having attained the age limit of liability to recall, cease to belong to the Res. of Off.:—

Lt.-Col. T. J. Wright, D.S.O.

Maj. R. B. Hole.

MILITIA

Maj. H. C. Bazett, O.B.E., retires on attaining the age limit, and retains the rank of Maj.

TERRITORIAL ARMY

Capt. W. C. Jack resigns his commn. on account of ill-health.

Supernumerary for service with the O.T.C.—Capt. W. M. Arnott, from R.A.M.C., Gen List, to be Capt.

Capt. J. J. D. Naismith to be Maj.

Lt. J. A. Blain to be Capt.

R. J. V. Battle and R. D. Burn to be Lts.

TERRITORIAL ARMY RESERVE OF OFFICERS

Capt. C. C. Taffs, from Active List, to be Capt.

ROYAL AIR FORCE

Wing Comdr. F. J. Murphy to R.A.F. Depot, Uxbridge, for duty as Senior Medical Officer and Officer Commanding R.A.F. Officers' Hospital, vice Wing Comdr. H. B. Porteous.

Wing Comdr. H. Burnet Porteous is placed on the retired list.

Flight Lt. A. S. Burns is placed on the retired list on account of ill-health.

Dental Branch.—Flying Off. H. M. G. Williams to Medical Training Depot, Halton, on appointment to a non-permanent commission.

Flight Lts. L. S. Everett, G. Gilchrist, and I. Mackay have been selected for permanent commissions in the Medical Branch, subject to physical fitness.

INDIAN MEDICAL SERVICE

Lt. (on prob.) J. F. A. Forster is restd. to the estabt.

The undermentioned appts. have been made in India:—

A.D.H.—Maj. E. W. Wade, D.S.O., R.A.M.C.

D.A.D.P.—Maj. H. J. Benstead, M.C., R.A.M.C.

The undermentioned officers have vacated appts. in India:—

D.A.D.P.—Maj. A. Mearns, R.A.M.C.

A.D.H.—Lt.Col. E. G. S. Cane, D.S.O., R.A.M.C.

PUBLIC HEALTH

A Salaried Service of Midwives

THE London County Council on Tuesday approved the proposal of the Joint Council on Midwifery to establish a salaried service of midwives. The report of the Joint Council had been forwarded to the L.C.C. by the Ministry of Health and had been considered by its hospitals and medical services committee. The Joint Council recommended in brief that the nursing of every maternity case should be conducted by a qualified midwife and that unqualified persons should no longer be permitted to nurse maternity cases for gain, it being laid on the local authority to provide midwives to act as maternity nurses for parturient women under a doctor's care unable to afford a trained attendant. The Joint Council proposed that a salaried service should be established under the local supervising authority (Midwives Acts) in all areas not already served by salaried midwives but without interfering with the continuance in practice of independent midwives. The Joint Council further proposed that midwives not accepted for salaried service or unfitted by age or infirmity should be entitled to compensation or pension. The L.C.C. supported the recommendation to establish such a service but, on behalf of the hospitals committee, Dr. Somerville Hastings was unable to accept the principle of compensating inefficient midwives. In the course of the debate Dr. Barrie Lambert stated that the present service was better than that of ten years ago by probably at least 50 per cent. although this improvement in the service was not reflected in any improvement in the mortality of childbirth. An amendment to ask the Ministry of Health to formulate a complete scheme for better organisation of maternity service in London was defeated. Sir Kingsley Wood told a deputation on Tuesday (p. 231) that he was awaiting the views of the L.C.C. and other local authorities before acting. It may well be he will take a more generous view in the matter of compensation, for without this it seems unlikely that any scheme will prove acceptable to organised midwives.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 13TH, 1935

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 0; scarlet fever, 1461; diphtheria, 910; enteric fever, 49; acute pneumonia (primary or influenzal), 393; puerperal fever, 33; puerperal pyrexia, 102; cerebro-spinal fever, 22; acute poliomyelitis, 8; acute polio-encephalitis, 4; encephalitis lethargica, 5; dysentery, 7; ophthalmia neonatorum, 85. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council on July 19th was 2661, which included: Scarlet fever, 747: diphtheria, 964; measles, 40: whooping-cough, 417; puerperal fever, 26 mothers (plus 7 babies); encephalitis lethargica, 270; poliomyelitis, 1. At St. Margaret's Hospital there were 26 babies (plus 14 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns including London, there were no deaths from small-pox or enteric fever, 17 (1) from measles, 5 (1) from scarlet fever, 14 (5) from whooping-cough, 30 (1) from diphtheria, 50 (8) from diarrhœa and enteritis under two years, and 19 (3) from influenza. The figures in parentheses are those for London itself.

Liverpool reported 7 deaths from diarrhœa, Hull and Birmingham each 3, no other town more than 2. Of the fatal cases of measles 4 occurred at Liverpool, 3 at Birmingham. Four deaths from diphtheria were reported from Liverpool, 3 each from Reading, Leeds and Birmingham. Leeds also reported 3 deaths from whooping-cough.

The number of stillbirths notified during the week was 300 (corresponding to a rate of 42 per thousand total births), including 45 in London.

AWARD TO DR. W. H. PARK.—Prof. Park, director of the bureau of laboratories of the New York City Health Department since 1894, has been selected as recipient of the Theodore Roosevelt medal for 1935, awarded for distinguished service in the administration of public office. He was the first to introduce diphtheria antitoxin into the United States and to make it available to the public, and he has been a pioneer in the discovery of the part played by carriers in the spread of infectious disease.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

PUBLIC HEALTH SERVICES

Sir Kingsley Wood's Review

On July 17th, in Committee of Supply on the Civil Estimates, **SIR KINGSLEY WOOD**, Minister of Health, sought approval for a total net estimate of £20,102,000, an increase of £313,000 on last year. A great part of the increase was, he said, due to the steady increase in housing grants, owing to the increased activities of local authorities on slum clearance; the remainder to the cost of the extra staff required in connection with slum clearance, &c., and to provision for restoration of salary cuts made in 1931. He went on to review briefly some of the main developments in health affairs of the last 25 years.

The great thing to note, he said, had been the awakening of the national conscience on health and housing affairs. There had undoubtedly been a widening of human compassion and the coöperative spirit. The nation itself had learned in many ways the supreme art of right living. Greater common sense was being shown in health matters, in clothing, dietary, and in the increasing use of daylight, open air, leisure and recreation, with the result that to many people in this country life was becoming longer and better—the greatest gift that civilisation could give. In 1910, for instance, the death-rate for all ages in England and Wales was 13·5 per thousand persons and 95,000 infants died under one year of age. Last year the total death-rate had fallen to 11·8, and the loss of infant lives under one year of age was reduced to 35,000, the lowest infant mortality rate on record. It was estimated that when Queen Victoria came to the throne the English boy child at birth had an expectation of 40 years of life. In the eighties it had risen to 44, and in 1910 to 51. In 1932, a generation later, it was 59. The growth of knowledge in medicine and surgery through all that period had been continuous. Typhoid fever, for instance, had been brought under control; it was at one time the scourge of nations and armies. The discovery of insulin in 1922 had revolutionised the treatment of diabetes. Orthopædic surgery was preventing the onset of crippling and treating cripples with new knowledge and by new methods. But cancer, still accounted for some 60,000 deaths last year, and a less malignant enemy, though regarded by many as Public Health Enemy No. 1, was the common cold.

The creation of the scheme of national health insurance had been one of the most remarkable developments in public health. The value of the benefits disbursed since 1911 was £480,000,000. In the last 10 years, over £150,000,000 had been disbursed on the statutory sickness and maternity benefits and over £90,000,000 in medical benefits. The scheme had survived the strains of the War, and the prolonged depression and unemployment of recent years. It was true that it had been found necessary to underpin the scheme, and to take steps to preserve its actuarial solvency. But it had stood the test of three valuations and it had been found practicable to allot £53,000,000 in additional benefits. Our national insurance system had now been adopted by 12 other countries from Norway in the north to Japan in the east.

But there was the unsolved problem of the unreduced maternal mortality rate. Its solution would require patience, constant research and active endeavour. The Departmental Committee which reported in 1932 suggested that at least one-half of the deaths might be prevented. The rate varied remarkably as between one area in the country and another. In West Ham, a poor borough, with a population of over 280,000, the maternal mortality rate over the period 1924/33 was 2·48 per 1,000 births. In Nottingham, a borough better off in many respects, and with practically the same population, it was 3·74. In Westminster, it was 5·63; in Marylebone 3·78; in Kensington 3·51; in Hampstead 3·48; and in Poplar 2·63. There had been no relaxation in the maternity and child welfare services on financial or other grounds. The number of visits paid by health visitors to expectant mothers showed an increase of 60,000, 240 more ante-natal clinics were provided and the number of women who attended those clinics rose by 49,000. The total number of attendances rose by 242,000, and the total number of women admitted to maternity beds in institutions provided or subsidised by local authorities rose by 29,000. They must, he added, go on vigorously with this work. They must persevere in the investigation of the causation of maternal mortality. He attached great importance to the midwifery service. Midwives attended approximately 60 per cent. of the confinements in this country, but their remuneration was low, and the poor pay and prospects reacted on the quality of entrants.

Sir **KINGSLEY** concluded with a summary of progress in rehousing the nation. There had been a record progress in the clearance of the slums. For the first six months of 1935, new houses for slum replacement had been sanctioned at the rate of over 6,000 a month in England and Wales, and at the end of June nearly 100,000 houses had been approved for this purpose, of which some 50,000, sufficient for about 240,000 persons, had already been completed. This was a great beginning of better things, especially when it was remembered that during the years 1875 to 1933, only 200,000 persons living in slum houses had been rehoused. There was further work still for the local authorities in the construction of new dwellings for families living in overcrowded conditions, in accordance with the proposals now before Parliament which he hoped would shortly be on the Statute Book.

VIEWS AND CRITICISMS

Mr. **GREENWOOD** said that, while it was true that there had been a very substantial improvement in the standard of the health of the people, he was surprised that no reference had been made to the question of malnutrition. Malnutrition was one of those subtle and creeping diseases the effects of which were not immediately seen, but from which a subsequent generation might seriously suffer. The houses built during the last four years would not, he said, bear comparison as regarded standards with the houses that were built before.

Mr. **JANNER** said that, although public attention must needs be drawn to the serious problem of maternal mortality, it was extremely important that the impression should not be created that child-bearing in itself was dangerous. The Departmental Committee on maternal mortality stated categorically that half the deaths in childbirth could have been prevented had a reasonable degree of skill been brought to bear upon the management of the cases, and adequate facilities for treatment been provided and utilised. Was the Minister satisfied, he asked, that the maternity and child welfare authorities were dealing actively and thoroughly with the position, and that the 174 who reported that they did not propose improvements were justified in their attitude, seeing that the mortality rates were so high? There was a strong feeling that post-graduate courses should be generally provided for practising midwives, that the salaries of midwives should be very much higher, and that midwives in rural areas should be subsidised and their numbers increased, so that they were more readily available and did not have to travel great distances. There was also a strong feeling that a doctor should be employed in every case, even though there might not be complications in the first instance, so that the doctor might be available in the event of any complication arising; and that obstetrical specialists should be available for all pregnant women. Mr.

Janner quoted Dr. Veitch Clark's view that midwives should form part of the externe practice of the maternity units of hospitals. They should be afforded the opportunity of living in a hostel or a home, should have an income guaranteed to reach a certain level by the local authority, and be linked up with ante-natal and post-natal clinics, and the hospital. During the last four years, there had been in Manchester a four-fold increase in ante-natal work; 50 per cent. of the pregnant women were now being seen ante-natally by the public medical service, and this increase in supervision had coincided with a fall in the death-rate from puerperal sepsis from 1·7 to 1 per 1,000. Mr. Janner asked the Ministry to urge local authorities to provide obstetricians who, day by day, would deal with cases definitely from the stand-point of a specialist. Full-time clinic officers should be appointed in as many instances as possible, and adequate hospital accommodation provided to enable them to follow each case when the actual time of confinement came.

Sir Francis Fremantle paid tribute to the work inaugurated by Sir George Newman; he welcomed the new chief medical officer, and asked for an assurance that his status remained unimpaired as a secretary to the Ministry of Health, with direct access to the Minister. During the past 25 years, he said, there had been a great change in the understanding of infectious diseases. In order to exterminate the microbe, they had isolated the patient, until it was shown that the same germ might exist in healthy carriers, and that at one time a microbe did not seem to do any harm and at another was brought suddenly into activity by a cold, a chill or an injury. It was the soil and the variations in the soil that mattered. What they had to do was to aim constantly at improving the physique and the health of the individuals that made up the population. The Ministry of Health, through the local authorities, had various means in which the promotion of physical health could be assisted, and he hoped the process would be continued now through the whole machinery of public health. They must recognise, too, that shortage of nutrition, more particularly among mothers, was bound to affect the next generation. Happily, there was little evidence of any increase of ill-health, either mortality or infectious sickness, from medical inspection in the schools in the depressed areas. There was malnutrition in particular families and districts where less attention was paid to the preparation of food. That was a point he hoped the Ministry would pursue with the Board of Education. More important than the selection of proper food was the power to cook it properly; a generation had grown up entirely ignorant of the art of cooking. To deal with maternal mortality, legislation, he said, would be required. The profession of the midwife must be made really attractive as a profession to the kind of girl that they wanted to have for this important service. He described the Rochdale experiment where, in the years 1932 to 1934, an intensive campaign had reduced the rate from 10 per thousand to 3·9. The same thing was repeated in the Rhondda Valley, where a special campaign, begun 18 months ago, had reduced maternal mortality to a third by paying attention to what everyone ought to pay attention to in the matter of confinements. Results could often be obtained by using existing machinery, but they had to bring machinery and an elastic mind together.

Mr. West called attention to the borough of Kensington where the infantile mortality last year was 93 per 1000, which was 50 per cent. worse than the average for London. The death-rate in North Kensington was 102 per 1000 compared with the rate in one East End borough of not more than 60 per 1000, in Poplar of 62 per 1000 and in Hackney of 54 per 1000. For the last ten years the death-rate in North Kensington and Kensington had been enormously above the average rate for Great Britain. There were one or two wards in Kensington which had a death-rate last year of 120 per 1000. If he had time he could show that not only the infantile death-rate but the diseases rate in respect of tuberculosis, fever, diphtheria and pneumonia averaged from three to four times that for London. Let the Government, he said, put some ginger into the councils who would not do their duty.

Mr. Levy appealed to the Minister of Health to see that the water supplies of the country were improved.

Dr. Addison said he was greatly comforted to hear the Minister say that he would take active steps to combat maternal mortality. They all knew that the training of midwives and so forth would take time, but by a few years of active work he believed that Sir K. Wood or his successor would be able to bring down the maternity death-rate. But he wanted to call attention to a matter of first-rate national importance. In the report on the school services in 1933 the concluding sentence ran:—

> "The physiological deterioration of the unemployed may appear at any time although it has not yet in any general degree appeared."

Dr. Addison believed that dramatic evidence of this physical deterioration was now emerging. He agreed that this deterioration was difficult to define; at the same time malnutrition began to appear gradually among children in the pre-school years, so that when old enough to go to school one began to find something distinctive in their condition. He said:

> The medical officer for Breconshire examined 2000 children in 15 schools in July, 1934, and he found that the "under-weights"—children of five classified as being under-weight from depressed areas—numbered half as many again as those from the areas which were not regarded as depressed. In Burnley the medical officer reported that the percentage of malnutrition among children had risen from 1·4 per 1000 in 1929 to 8·3 in 1933, notwithstanding the provision of free meals.
>
> The report of the Preston medical officer contained this:
>
> "Put scientifically, the industrial situation has deprived people of first-class proteins, fats and vitamins. In plain words, bread, jam, margarine and tea have taken the place of milk, meat, eggs and fresh fruit. In the districts where unemployment is most marked the results of poverty are very definitely reflected in every class of the school. Taken as a group the children are undersized, pale, listless, flabby and mentally dull."
>
> In Pontypridd the medical officer's report stated:
>
> "Long-continued unemployment in the basic trades has led to a large number of families becoming dependent upon transitional payments or public assistance. There is imminent danger of this continued low level of subsistence leading to malnutrition and physical deterioration among the children of the unemployed."

These were a fair sample of the reports which had emerged in the last 12 months or so when there had been time for the malnutrition associated with unemployment to begin to make itself manifest. He would urge that the report of the President of the Royal Society and other scientists that was made to the Government last year on the nutrition of children and kindred subjects should be published.

A most precise inquiry had been conducted at Newcastle among the children of those who had been out of work and of those who were more well-to-do.

> Among the well-to-do 25 per cent. of the children were above the normal height, whereas in the industrial or poorer classes only 2 per cent. were above, and 47 per cent. were below it. A remarkable thing had emerged during the last two or three years from these nutritional inquiries in the poorer areas, and that was the wide extent of anæmia among children. It arose only gradually and imperceptibly, gradually developing as a result of improper or insufficient dietary. In the Newcastle case a certain standard was taken. Twenty-three per cent. of the industrial classes and those who had been unemployed were below a very low standard. None of the other children were below and 75 per cent. of them were above it. In this inquiry, Dr. Spencer first came across these children by accident, because he was looking out for cases of rickets to treat

with the modification of a new scientific remedy. In 1921 and 1923 it was very difficult in hospital out-patient rooms to find rickets; but in Newcastle 44 cases of rickets were found quite easily. In the first 40 cases, as they came in, when their family circumstances were traced back, in every case the parents were out of work. Cases throughout the country which had been investigated all indicated the same kind of thing, that about 60 per cent. of the expenditure on food of the poorer people was spent on cereals, bread and so on, which did not contain certain elements necessary for full healthy development, and the absence of which explained rickets, dental caries, pyorrhœa, and so on to a large extent. These people could not afford eggs, milk, fresh fruit and vegetables.

If, said Dr. Addison, the feeding of the unemployed and the allowances to be made by the new Board were accompanied by a proper diet policy, he would undertake to say that in a few years' time the average stature of British children would be up by, say, a couple of inches, and they could wipe out rickets together with 50 per cent. of the dental caries and pyorrhœa.

Mrs. TATE said the spending of money alone would never save one mother's life in the country. The maternity mortality problem was not as simple as that. Medical knowledge had advanced out of proportion to the availability of that knowledge to the public, which would come when they had a proper coördination of services, proper continuity of services, and, above all, proper training. In the area served by Guy's Hospital the maternal mortality figures had been brought down to one per thousand because there was a trained staff attending the people. The position in the country to-day was the danger of a less trained staff. Even Guy's students and midwives were getting only half the material on which to learn laid down as a minimum by the General Medical Council. Ante-natal and post-natal clinics were useless unless staffed by experts. One of the main faults lay with the appointment boards of hospitals which insisted before they gave good jobs to nurses that they should have a C.M.B. certificate, whether or not they intended to practise midwifery. If the small supply of material was used by nurses who were never going to practise midwifery it meant taking it from those who were. Mrs. Tate referred to the report of the Committee on Fractures, which showed a complete lack of organisation in this country in regard to fractures in almost all the general hospitals, with serious loss of money not only to the workmen themselves, but to the insurance companies. There were two well-organised hospitals for fractures in this country: Ancoats Hospital, in Manchester, and the Liverpool Infirmary. To quote only one example: in 482 cases of Colles's fracture in organised hospitals the disability period averaged seven weeks, and the number of cases permanently incapacitated was two. In unorganised hospitals, in 38 cases of the same fracture, the average period of disability was twenty-nine weeks, and the number of cases permanently incapacitated was nine. Those figures gave serious cause for thought. She hoped pressure would be brought through the Ministry and the insurance companies to see that a continuous and efficient service for accidents was inaugurated. One of the causes of ill-health among women in the urban and industrial areas was, said Mrs. Tate, the tremendous amount of abortion. Hon. members might or might not approve of birth control clinics, but let them face what was going on.

Viscountess ASTOR said the fall in the birth-rate meant that they had to take particular care of the children that were born. About 80,000 children were born each year, and of that number 2500 were still-born, 2700 died under the age of 1 year, 6700 died between the ages of 1 and 2, and 6600 died between 1 and 5. Those figures were too high. It was in this connexion that the infant welfare centres were so important, but although this country was ahead of nearly every other country in the world in that respect it had not enough infant welfare centres. There were 1,750,000 children between the ages of 2 and 5, and of that number 200,000 lived in overcrowded conditions of 3 or more persons per room. Out of every 100 school-children examined 15·9 needed medical attention, 15·4 needed observation, nearly half showed rickets. They must increase the number of infant welfare centres and open-air nursery schools. They must face the fact that a high percentage of maternal mortality was due to attempted abortion. There was only one ante-natal clinic for every 5500 women of child-bearing age, and some of these clinics were not properly distributed. How many local authorities were prepared to make any provision for scientific birth control? Ignorance was the chief cause of the practice of abortion. Women were unable to get advice. Local authorities had been allowed to give such advice since 1934, but of the 1200 local authorities only 60 had clinics, though it was true that about 150 more referred patients to voluntary agencies and there were 54 voluntary clinics in England and Wales. A great deal of suffering could be prevented.

Mr. BATEY referred to a letter of Dr. G. F. Walker, of Sunderland, to the *Times* of Dec. 11th, 1934, which led to an enquiry by the Ministry of Health. By far the worst part of the County of Durham referred to in Dr. Walker's statement was the south-west, but no enquiry was held there into the alleged malnutrition and deterioration. There was no doubt in his mind that in that county at the present time thousands, including children, were suffering from under-nourishment. He urged a fresh enquiry.

Dr. HOWITT called attention to the work done by the almoners attached to hospitals. There were at present, he said, many people who called themselves almoners, and who did excellent work but were not trained almoners as he would wish them to be. In hospitals to-day, as far as he knew, there was nobody who had a true knowledge of all that could be done for a patient. In these days they must have expert knowledge of all the charitable help and government help open to a patient. So far as he knew, no man or woman on the staff of a hospital had that knowledge to-day. Neither had any of the hospital officers. To ensure that hospital almoners should be able to see that there was no waste in hospitals, the Institute of Hospital Almoners selected the right type of person to be almoners. These persons had to obtain a diploma of Social Science, which meant two years' work and the passing of examinations, say at the School of Economics. They then had to work for four months in a charity organisation society and subsequently for ten months in a hospital almoner's office. After a training lasting a little over three years such a woman, who to start with must be well-educated, had really an idea how she could do scientific social service. Dr. Howitt instanced the value of hospital almoners in obtaining charitable or governmental assistance for patients who would not otherwise be able to carry out the medical or surgical advice given them by the hospital staff. In cases of tuberculosis, he said, it was essential that the relatives of a patient should be brought to the hospital in order to ascertain whether they had contracted the same disease. The almoner brought all these contact cases to the hospital to be examined, and she also saw that the home was made fit for persons who were subject to tuberculosis to be properly looked after. He hoped the Ministry would see that all hospitals in this country had properly qualified almoners attached to them.

Dr. O'DONOVAN said he had a familiar working knowledge of the poor, and he had never got the impression that either the poor or the rich had, since the War, been unfamiliar with birth control knowledge. The supply of birth control goods and apparatus was a competitive and big business. To suggest that abortion was practised, leading to the frequent death of women, and this through lack of birth control knowledge, was in his opinion a misreading of the facts as they were. There was to-day a tremendous propaganda to the effect that marriage need not be associated with the production of children, and once that idea became bitten into the public mind there was a demand that contraceptive practice should be efficient. The demand for efficiency became almost a passion, and if birth control through contraceptive practice failed, then the woman who found herself pregnant demanded that abortion should complete what birth control had failed to do. The one grew out of the other; and when they added to that, through the same advocates, the policy of sterilisation they had a trilogy of birth control, abortion, and sterilisation which, if imposed on an unwilling Ministry, would turn it from a Ministry of Health to a Ministry of Death.

Lieut. Col. MOORE said there were very few plastic surgeons, and they were overwhelmed by demands upon their skill and service. Why should they not devote some of the resources at the disposal of the Ministry to assist in the formation of a special hospital where people disfigured by nature or by accident could find treatment. He suggested this should be done in conjunction with the L.C.C., and other county hospitals.

Mr. STOREY suggested to the Minister of Health, that the time was ripe for an inquiry into the whole hospital system of the country, so as to provide a coördinated plan.

MINISTERIAL REPLY

Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, said he wished an occasion would arise when the sterilisation of the unfit could be more freely ventilated. They wanted the guidance of public opinion. The policy of the Ministry of Health was that it was wrong for a maternity and child welfare centre, or a clinic for the treatment of sick persons, paid for out of public funds, to be used for giving contraceptive advice, except in cases where further pregnancy would be injurious to health. In reply to Sir F. Fremantle he said that the chief medical officer of the Ministry would have the status of a Secretary in the same degree as his predecessor, and the same right of direct access to the Minister. With regard to the points raised by Mr. West about infantile mortality in Kensington, he had in his hand a letter from the medical officer of health which showed how careful one ought to be in quoting statistics.

In one divison of Kensington—Holland Ward—there was an infantile mortality rate of 133 per thousand. That was very high, and was accounted for by the fact that there were 18 deaths. The letter from the medical officer showed conclusively that of these 18 deaths only 3 could have benefited by the maternity and child welfare services, and that, in fact, only 3 availed themselves of them. Of the 18 deaths, a considerable number were of children who had been adopted by institutions in Kensington; they came from outside. He had not the slightest doubt that much of the high rate in Kensington was due to bad housing conditions, but the housing problem was being tackled there as vigorously as in any other London borough.

Mr. Shakespeare challenged the suggestion of Dr. Addison that the Government had economised on the care for children and mothers during the last four years. In every circular that they had issued they had made it plain that although economy was necessary in 1931 the work of maternity and child welfare centres must be pressed forward. Dr. Addison had also asked that the Government should publish the report of the Economic Advisory Committee. This was a confidential report to the Cabinet. If published, the whole purpose of the Committee and the value of their reports would be lost. As a result of the last report the Government had enlarged the Advisory Committee on Nutrition set up a few years ago and turned it into a Standing Committee, under the chairmanship of Lord Luke, consisting of expert dieticians, statisticians, medical men and people with a great knowledge of public health and social conditions. The question of nutrition had hardly been touched. One would expect that with continued and prolonged unemployment there would be a slow deterioration of health, and the Ministry were always looking for that. Mr. Batey had raised the question of the report of the inquiry on Dr. Walker's statement about conditions in Durham. Dr. Walker was associated with that report, and if he asked the investigator to go anywhere he went, and this was what the report said:—

> "While we have found in the area under review a considerable incidence of sub-normal nutrition and some incidence of malnutrition, our investigation shows little evidence of any increase of disease and none of increased mortality. The physical condition of the majority of individuals passed under review is good. Realising the long-continued economic stress to which this population has been subjected and with knowledge of the home conditions of many we have often been surprised at the high standard of health and courage which has been maintained."

The report did show that the condition of adolescents from 14 to 16 was far from satisfactory, and the Government took steps to rectify it. They instructed the local authorities to pay special attention to giving relief to families containing adolescents. When a person was malnourished very often it did not mean that more food would rectify it; more food might accentuate the digestive disturbance. What was wanted was advice and instruction so as to secure that the right food was taken and that it was properly cooked. Mr. Shakespeare quoted an experiment recently conducted in London. Dr. Simpson in 1934 examined the condition of children in some of the poorer areas in London. He took a sample of malnourished children and he found that 7 per cent. of a certain batch came from the homes of the unemployed and in another area, another school, he found that another 7 per cent. of malnourished children all came from homes where the means were substantial and the parents were employed. What was vital was that the Ministry should be constantly on its guard. Whenever they received reports from medical officers of health or any signs of malnutrition they immediately got into touch with local authorities. The machinery of public health in this country, both national and local, had so far proved adequate.

Work of Home Office: Factory Accidents and Industrial Diseases

ON July 16th, the House of Commons went into Committee of Supply on the Civil Estimates. CAPTAIN BOURNE was in the chair.

On a vote of £396,253 to complete the sum necessary for the salaries and expenses for the Home Office, SIR JOHN SIMON, Home Secretary, recalled that just 20 years ago he was Home Secretary. Since then there had been great extensions in the work of the Home Office, for example, in the control over dangerous drugs.

Referring to the annual report of the chief inspector of factories for 1934, he called attention to the excessive number of accidents among juveniles, though happily the fatality-rate was low throughout the whole of industry. The chief inspector pointed out that the true solution lay in voluntary efforts of employers and others, and in the better training and supervision of boys and girls in the early days of their employment. SIR JOHN had sent to the National Confederation of Employers' Organisations, inviting them to a conference with the department on this subject. The report of the chief inspector also illustrated the fact that since the war the work of the factory department had developed in several new directions.

Mr. RHYS DAVIES moved the reduction of the vote by £100. He asked the Home Secretary to investigate the problem of whipping boys by the order of the court; he hoped the department would continue to discourage the practice. The worst feature of the annual report referred to was the increase of reported accidents from 113,260 in 1933 to 136,858 in 1934, roughly an increase of 5,600, fatal accidents having increased by nearly 100—i.e., from 688 to 785. The percentage increase of reported accidents was far higher than the percentage increase in the number of work people employed.

Industrial diseases also were for the most part increasing; 30 more new cases of lead poisoning occurred than during the previous year and six more deaths. Even in the painting of buildings there was an increase in lead poisoning, in spite of the passing of an Act of Parliament a few years ago, dealing with the use of white lead in paint. The most extraordinary anomaly of all was that while safety organisation in factories was growing there was almost a proportionate increase in industrial diseases and accidents. The only redeeming feature was the declining rate of silicosis in the pottery industry. There was also a serious increase in industrial disease among those employed in chromium plating and those handling pitch, tar, and oil; 423 persons had died from pitch and kindred cancers from 1920 to 1924.

Mr. PIKE asked if Mr. DAVIES would say what was the cause of the increase in the chromium plating figures?

Mr. DAVIES replied that medical men were, he believed, inquiring into this question. Cases due to fuels and gases were 179 in 1934, compared with 149 in 1933, with 21 deaths in 1934 against 14 in 1933. Negotiations had been proceeding for some time past between the Home Office and the employers in the Lancashire textile industry, regarding men who suffered from asthma and bronchitis consequent upon dust in card rooms. He believed that the Home Office had been doing its best. It was very difficult to schedule this disease for workmen's compensation. He welcomed the efforts to secure better lighting in factories. If the Home Office could not by ordinary pressure bring the factory owners up to standard in this connexion, he hoped that they would ask for Parliamentary powers to deal with them.

Referring to the circular issued to local authorities preparing the population for an attack from the air, he said he doubted if a circular so awful in its implications had ever been issued by a Government department in this country. Mr. DAVIES knew of no device which would effectively safeguard human life once aircraft began to drop bombs on a civil population. The clamour for gas masks following an issue of the circular would lead to the same problem of profiteering in gas masks as they had had in the manufacture of aircraft, unless the Government took immediate steps to prevent it.

Mr. PIKE said that Mr. DAVIES had failed to read the significant part of the report concerning lead poisoning. The sentence read: "The reduction in cases of lead poisoning in the past few years has not been maintained; there is an increase of 30 over last year's figures, mostly among pottery workers, as foreshadowed in the annual report of 1933." The chief inspector attributed this increase mainly to the increase in the building of houses and in some measure to an influx into the industry of untrained workers, under the supervision of persons not yet fully alive to the high standard of cleanliness required under the regulations to control the lead risk. It was stated in the report also that of the 26 cases in the pottery industry, 16 occurred in the manufacture of highly decorated tiles with leaded glaze, which carried less liability to silicosis but more to lead poisoning than did the manufacture of other tiles.

Similarly the report stated that the increase in the number of cases of chrome ulceration was attributable to the further extended use of the process of chromium plating.

Mr. TINKER said that the Home Secretary had power by regulation to include in the schedule of industrial diseases any disease which he thought should be brought into the schedule. Workmen's compensation had been built up by that method. Many members, especially those who represented industrial areas, had come across cases of Dupuytren's contraction, which seemed to be brought about by the thickening of the tissues in the centre of the hand, origin by excessive use of a spade or pick. One man sent him a letter over 12 months ago now had h in an advanced state of contraction, and in a m or two he would have to give up work. There nothing in the Workmen's Compensation Ac protect him. His medical man told him that he entitled to compensation because his condition been brought about by his employment, and the went to his trade union official. They looked up schedule of diseases, but the term was not include it, and the man could not get compensation. Home Office declared that there was not suffic evidence to warrant the inclusion of the disease. hoped that the new Minister would not let the ma stop at that.

Another question was that of medical refe When a man was regarded as recovering, the empl had to examine him, and if the man was well on way to recovery he could serve him with ten d notice. The man could get a medical opinion, w might be that he was not recovering. The ma was then referred to a medical referee. It pas through the register of the county court, and at end of ten days came before a medical referee examination. He had no fault to find with the met up to that point; his complaint was in regard to length of time, sometimes one, two, or three mon that elapsed after the ten days before the man examined by the medical referee. After such a l period much if not all of the damage might h passed away, and in that case the man would nothing. That gave rise to difficulties in signing at the Employment Exchange, because the man not fit for work and could not claim unemploym benefit. When he was fit for work he received compensation and no unemployment benefit.

Could not the Home Office lay it down that at end of ten days the man should be paid his comp sation until he went before the medical refere That would certainly hurry matters up. Or could th not say that at the end of a reasonable time, say a fo night, if the man had not then been before the medic referee, owing to the fault of the employer, comp sation should be paid to him until he did go before t medical referee? If that could be done, these ca would come before the medical referee with extre rapidity.

At present, there was only one medical referee, w alone had the power to decide a man's fate, and ev though his condition might change from what it w when he came before the medical referee, the man h really no case in law. He could go before the coun court judge, who could hold that there had been change in his condition. The Miner's Federati took such a serious view of this matter that they ha asked the Home Office whether, at least in extren cases, there could not be more than one medical refer to decide on the condition of the man.

Sir ARNOLD WILSON drew attention to the i creasing frequency of accidents in electrical lifts large towns; he held that these should be notifie Hundreds of people—mostly boys—were killed maimed in our cities every year by lift acciden The lift was becoming more and more a p of our lives, and it was not safe to leave the matt any longer to chance and the coroner. The ch inspector of factories had referred to the bad lighti which was so common in factories. Instead appointing more factory inspectors and devisi fresh laws and regulations, the Home Secretary shou induce the great firms in this country who suppli electrical equipment to spend a few thousand poun on a special campaign of advertisement and educati and instruction, particularly of small firms, into t numerous new ways of lighting which could be intr duced, often at a great saving, even into the olde factory. He endorsed Mr. TINKER's plea in rega to the subject of a medical referee sitting alone. Le poisoning and chrome ulceration were largely due the absence of adequate medical supervision on t spot at the right moment, as was stated by the chi inspector of factories. The doctor was coming more and more into our lives and his position in such matters should be that of an assessor or witness, who should give his technical advice, and the final decision whether a man was or was not suffering from a given disease—a matter upon which his whole future depended—should be given by a judicial authority, a referee—someone learned in the law—who had to assist him, on the question of evidence, one or more medical men of high repute sitting as assessors, and not acting as judges. Dupuytren's contraction was an admittedly obscure disease and he could quite understand the difficulty of the Home Secretary's predecessor in reaching a decision that this was a proper disease to schedule, but he could see no reason why, with the Industrial Health Research Board at the disposal of the Home Office, every single reported case of that disease should not be specifically examined by a doctor appointed by the Board. If this disease was thoroughly examined a final decision could be reached within a year or so, and once reached could be given retrospective effect. We had mighty efficient scientific machinery, and he was by no means satisfied that we were making the best possible use of it.

Sir A. Wilson had not seen a copy of the air raid circular, but he felt confident that there was far less known about the probable effect of many of these terrible weapons than was popularly thought. He believed that the best remedy was attack, but that was obviously outside the Home Office vote. Meantime, he urged the Home Secretary in any public references not to increase the public fears.

Mr. Lyons pointed out that incidental risk was attached to various new kinds of work. For example, chromium plating was now so much used that manufacturers on a large scale no longer bought their chromium-plated material and put it on to their own article, but established their own chromium plating plants. That new type of work offered a new danger to employees. He welcomed the suggestion that proper medical inspection and constant medical guidance could prevent increased accidents. He suggested to the Home Office that any concern utilising a new type of invention, such as chromium plating, should be specifically asked not to wait for fortnightly or monthly inspections, but to make the period very much shorter, and to introduce medical supervision daily, if necessary. Finally, he asked the Home Secretary if the time was not now ripe for a real review of the schedule of industrial diseases.

Mr. Fleming called attention to the provisions of the Drugs Act of 1920. The Department, he said, had been pressed from all quarters to tighten up the administration, and there had been a report from the Poisons Board with regard to the people who should be qualified and permitted to dispense drugs. While protecting the public as far as possible, the Home Office ought to take the greatest care to see that, if it acted upon that report, it did not cause undue unemployment. If the only people allowed to supervise the manufacture of poisons to be used medicinally in this country were members of the Institute of Chemistry, men and women more qualified than members of this institution would be debarred from doing the work which they were doing to-day.

Mr. Cleary said that the Mersey Tunnel was 2½ miles long, and there was a widespread opinion that tunnels of such great length and holding capacity would provide safe refuges in an air raid. On the other hand, if poison gases heavier than air were used, these tunnels would become death traps. Referring to the Poisons Board, if members of the Institute of Chemistry alone were to have any voice or control in the manufacture of poisons this would exclude 60 per cent. of the chemical profession, including the members of the British Association of Chemists, and this would obviously be an injustice and a hardship.

Mr. John emphasised the need of expanding the schedule of industrial diseases. The last 30 years had shown that from time to time new diseases were discovered, consequent upon changes in occupations, which were not scheduled under the Compensation Act. Experience had proved the need not only of expanding the schedule, but of revising some of the orders already in existence. Great progress had been made with respect to orders dealing with silicosis during the past 15 years, and last year's order was a material advance. It provided that a workman certified as suffering from silicosis was entitled to compensation, but there were two or three difficulties. One was that the order was not retrospective. Hundreds of men who had been certified as suffering from silicosis, could not establish their claims, merely because they were suffering from silicosis prior to the date mentioned in the order, namely, October, 1934. The order was confined to underground operations, and the large number of surface men certified as suffering from silicosis could not claim compensation. No matter when or where a man contracted the disease such certification ought to entitle him to compensation.

Then there was the question of aggravation and acceleration. If a man died following an accident, and the doctor certified that the accident had aggravated death, the widow and orphans were entitled to compensation; but if he died of heart failure or pneumonia, notwithstanding the fact that the doctor certified that silicosis had aggravated or accelerated death, the widow and orphans were not entitled to compensation. A disease similar to silicosis was anthracosis. It was getting very prevalent in the coalfields, and medical science through the College of Physicians was taking a keen interest in it. It had been found that a large number of men were suffering from anthracosis, which was contracted through the inhalation of coal dust. In years gone by, it was certified as bronchitis. He asked the Home Secretary to make investigations to ascertain to what extent this disease existed in the coalfields, and to see whether it was possible without much delay to make an order to enable a man suffering from anthracosis to be entitled to compensation. They had not much complaint against the policy adopted with respect to the medical examination of persons suffering from silicosis. There were three medical boards responsible for silicosis cases. The Home Secretary had been asked to consider extending the principle of medical boards to all cases of accidents. The medical referee had too much power; in fact, he was judge, jury, House of Lords and court of appeal in one. Was it not possible to extend the principle that applied to silicosis to all other accidents, so that the individual would have the satisfaction of being examined by a medical board It would mean the removal of a great deal of delay.

Then there was the question of prevention. The Home Office and the Mines department had been doing a great deal of good work in investigation and research into the prevention of accidents, but there was no coöperation or coördination between the two departments. The Mines department had been making investigations and research into the prevention of silicosis and a good deal of inquiry was made into the foam that had been invented to absorb the dust and into dust traps. An exhibition had been held at the Home Office the other day dealing with the prevention of accidents, but once an exhibition was held and inquiries and research had been conducted, nothing further was done. He would like to see more coöperation between the departments, and that when a particular means of prevention was approved, employers should be compelled to adopt it.

Captain Euan Wallace, Under Secretary, Home Office, replying to the debate, said, with regard to air raids, that responsibility of the central Government towards the civil population could not be ignored. This circular was only a preliminary, and would be followed up by conferences, and by the issue from the Air Raids Precautions Department of a series of technical handbooks. The congregation of people into places like the Mersey Tunnel, or the tube system of London, obviously held elements of the very greatest danger. It might be impossible to-day to secure complete immunity from aerial attack, but mitigation of its effects was well within the bounds of possibility, and there was no reason for the citizens of this or any other community to sit down with folded arms and wait for an assault.

Reference had been made to what was regarded as the deficiency in the staff of the factory inspectorate, but the 254 inspectors which they had at the moment were 14 more than they had last year and 7 above the maximum number they had ever had. On the advice of the expert Departmental Committee there was not at present sufficient evidence to justify putting Dupuytren's contraction on the schedule of industrial diseases. In order to be put on the scheduled list, it must be a disease which was definitely shown to be due to occupation and to nothing else. They could not, for instance, put asthma or hay-fever on the schedule, because they arose from some other causes than that of employment, but the Home Office would keep this question, and all other medical questions of the kind, very closely under review. With regard to the questions about medical referees and delay in decisions, the announcement that they proposed to set up a departmental committee to examine that and several other cognate questions would give general satisfaction.

The increase of accidents, regrettable as it was, must definitely be ascribed to (1) the general expansion of trade; (2) the fact, that men were coming back into work after long periods of unemployment; and (3) the fact that a general industrial reorganisation was now proceeding in this country as a result of a very large number of new processes. The fact that a high proportion of the accidents occurred among juveniles appeared to him to indicate rather failure of the human factor than inadequacy of the material precaution.

The motion to reduce the vote was negatived by 121 votes to 40 and the debate was adjourned.

Criminal Lunatics (Scotland) Bill

In the House of Commons on July 19th, when this Bill was being considered on report, Mr. JAMIESON, Lord Advocate, moved an amendment to clause 4, the effect of which he said, taken along with the amendments inserted in Committee, would be that where a person serving a sentence was found to be insane, but his insanity was such that he was not suitable to be sent to an ordinary asylum, he would be sent to a criminal lunatic asylum and the opportunity would be given to have him examined by his own medical man. The doctor's report would be considered by the Secretary of State, who would review the whole circumstances and make such order as might be necessary on the expiring of the sentence; if the person was not yet fit to be set at liberty on account of his insanity, and not fit to be sent to an ordinary lunatic asylum, certification to that effect would be given by two medical practitioners, one of whom was not to be in the prison service. An opportunity would be given at that time for the person to be examined by his own doctor. Again the Secretary of State, on receiving the reports, would consider the whole of the circumstances before making an order. The Lord Advocate added, that he understood that with these amendments the Bill was noncontentious. The amendment was agreed to and the Bill was read the third time and passed.

Precautions Against Air Raids

In the House of Lords on July 23rd, Lord MORLEY raised the question of the Home Office circular recently issued with regard to precautions against air raids. He said that the gas masks which would be available were of psychological value only. The Government would have to take the question of gas masks much more seriously. They must consider adults, children, and animals. Every mask was quite useless against chlorine gases.

The Earl of FEVERSHAM (Lord-in-Waiting) said that the Government most strongly deprecated the statement that there was no defence against gas attack, and that therefore it was useless to do anything at all. He had been informed by expert advisers that it was perfectly feasible to provide protection against gas. In fact it was often easier to provide this protection than protection against high explosive bombs. The steps which the Government contemplated would go a great way to minimise the dangers of this form of attack. Stories of gas possessing qualities against which no respirators were a protection were without foundation. The Government were actively engaged in designing a form of respirator which would supply adequate protection against gas for members of the general public. It was an essential requirement that the respirator should be available at a low cost. Such a respirator would provide adequate protection, in addition to such measures as people had been able to take to make some part of their houses gas-proof. In the recruitment of the humanitarian services, rescue work, first-aid treatment of casualties, and decontamination, the Government would be dependent to a large extent on the British Red Cross Society, the Order of St. John, and the St. Andrew's Ambulance Society, who had been good enough to say that so far as practicable they would place themselves at the disposal of both the central and the local authorities to supplement official resources. Respirators and protective clothing would be supplied to persons engaged in air raid services.

HOUSE OF COMMONS

WEDNESDAY, JULY 17TH

Hospitals and Electric Lighting Failures

Mr. BERNAYS asked the Minister of Transport whether, following on the recent failure of the system of electric supply in London, he would consider legislation making it compulsory for hospitals, theatres, and other public buildings to install an emergency automatic system.—Mr. HORE-BELISHA replied: I understand that the licensing authority ordinarily make it a condition of the licence that in places of public entertainment there shall be a system of dual lighting. I would not feel justified at this moment in interfering with the discretion of hospitals, who being aware of their own needs would naturally provide for them to the full extent of their economic resources.

Beddington Sewage Works

Mr. DORAN asked the Minister of Health if he was aware that similar insanitary conditions as experienced in 1934, emanating from the Beddington sewage works, were now recurring in the Mitcham, Beddington, and West Croydon areas, and during the recent hot weather it was impossible for the residents to frequent the commons in these respective districts owing to the prevalence of very offensive odours; and if, in view of the failure of the interim measures taken by the Croydon corporation, he would use every means in his power to put an end to this nuisance.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend has arranged for an inspector to visit these works to-day in order to examine the conditions.

Rules under Pharmacy and Poisons Act, 1933

Sir ERNEST GRAHAM-LITTLE asked the Home Secretary whether, in view of the hardship caused by the exclusion of university graduates in chemistry, unless they were or became members or associates of the Institute of Chemistry, from the list of persons authorised to undertake or supervise the manufacture of pharmaceutical preparations containing any poison used in the internal treatment of human ailments, he would instruct his department to add to the categories of persons so authorised (Report of the Poisons Board, Cmd. 4192, Appendix II., Rule 27) persons qualified by the possession of degrees testifying competency in chemistry, issued by accredited universities, without being required to seek membership of the Institute of Chemistry.—Sir JOHN SIMON replied: Notice of my intention to make rules under the Pharmacy and Poisons Act, 1933, including the rule to which the hon. Member refers, has been published in accordance with the Rules Publication Act, 1893, and I shall not be in a position to take any final decisions until after the expiration of the period during which the draft rules are open for representations to be made to me. The hon. Member may rest assured that all such representations will be most carefully considered.

THURSDAY, JULY 18TH

Free Milk and Meals for School-children

Captain SPENCER asked the President of the Board of Education what, if any, representations had been made to him as to the effect of Circular 1437, dealing with the discontinuance of free milk and meals to school-children in certain cases.—Mr. OLIVER STANLEY replied: Certain representations have been made to the Board in the matter. The Board have made it clear that, before free meals or milk are withdrawn, a sufficient period should be allowed to elapse for the child's health to become firmly established. The Board have also stated that they would regard it as reasonable to take into account the conditions under which the child is living, and to take special precautions where those conditions are such that deterioration is probable if the meals are discontinued.

Captain SPENCER: May we take it that the statement in a Manchester newspaper that children must be half starved before they receive such assistance is totally untrue?—Mr. STANLEY: My hon. friend will see from the answer that that statement is completely without foundation.

Mr. MORGAN JONES asked the President of the Board of Education whether his attention had been called to the instruction given by the Conference of the Association of Education Committees to its executive to go into the legal aspect of Circular 1437 in relation to the selection of children for free milk and meals; and whether, in view of the opposition of local education authorities to the circular and the resolution adopted by the Council of the British Medical Association that the onus should not be placed upon a medical officer of determining in every case that a scholar was presenting evidence of subnormal nutrition before free milk or meals are provided, he proposed to withdraw it.—Mr. OLIVER STANLEY replied: I am aware of the instruction in question; I am not, however, prepared to withdraw Circular 1437. I am satisfied that the system recommended by the Board provides the most effective means of securing that meals or milk are supplied to children who need them in order that they may obtain full advantage from their education, and that under any other system many such children may be overlooked. While the system recommended by the Board is opposed by some local education authorities, there are many authorities who select children on the basis outlined in the circular.

Dr. ADDISON: Has the right hon. gentleman availed himself of the advice given by a number of experts a year ago as to the necessity of these children receiving milk?

No reply was given.

Aged Recipients and Public Assistance

Sir JOHN POWER asked the Minister of Health if he could furnish an estimate of the extent to which the increase in the population of persons in receipt of public assistance in the last 25 years arose from the greater longevity of the population.—Sir KINGSLEY WOOD replied: The number of persons who are over 65 years of age and are in receipt of relief is considerably smaller now than it was in 1906, owing to the introduction of old age pensions. The greater longevity of the population has, no doubt, had the effect of preventing a larger reduction, but I regret that I have no means of estimating that effect statistically.

MONDAY, JULY 22ND

Retained Foreign Body and a Pension

Mr. WHITESIDE asked the Minister of Pensions whether he was aware that Mr. Henry Fisher, of 9, Brompton-row, Dewsbury-road, Leeds, was originally granted a pension of 24s. a week, but that this was reduced to 8s. a week in 1922; that he was totally unable to work, and that, in the view of the highest medical authority at Leeds Infirmary, his disability was due to a piece of shrapnel lodged in his chest; and would he consider, therefore, increasing Mr. Fisher's pension.—Mr. R. S. HUDSON replied: In view of the strong opinion expressed by the surgeon at Leeds Infirmary, the whole case, including opinions in favour of the claim, was submitted to an eminent independent specialist nominated by the President of the Royal College of Physicians, who confirmed the view of my department that on the available evidence it could not be said that Mr. Fisher's condition was due to the presence of a retained foreign body. In the circumstances I much regret that I cannot see my way to adopt the course suggested.

Future of Wyton Sanatorium

Mr. THORNE asked the Minister of Health if he had yet replied to the Huntingdonshire county council's request for permission to sell Wyton sanatorium for consumptive children and adjacent lands, comprising nearly 200 acres to the Air Ministry; and where it was proposed that the children in question were to be sent and the price paid for the lands and buildings by the Air Ministry.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Health, replied: My right hon. friend understands that the county council are considering whether, in view of the reduced demand for beds for children, this sanatorium is still needed for its present purpose, but they have not yet submitted any proposals to him.

Salaries of Medical Officers of Scottish Board of Control

Mr. GUY asked the Secretary of State for Scotland whether the salaries of the medical officers employed in the General Board of Control for Scotland were fixed irrespective of sex.—Sir G. COLLINS replied: The answer is in the affirmative, with the qualification that the present woman deputy commissioner retains a personal salary until her appointment as commissioner takes effect in October next.

VICTORIA HOSPITAL, SWINDON.—It is hoped to launch a private ward league here to extend the operation of the contributory scheme to higher paid workers.

ALL-INDIA OPHTHALMOLOGICAL SOCIETY.—At its fourth conference, held at Madras in April, this society submitted a series of resolutions to the notice of the authorities concerned in British India and the Indian States. These asked that steps should be taken to ensure that practitioners, midwives and others concerned in the conduct of childbirth should possess a practical knowledge of the prophylaxis of ophthalmia-neonatorum; that medical officers employed on nutritional research should report on conjunctival xerosis or keratomalacia as seen in hospitals, and make practical suggestions as to how the food defects responsible may be met; that the Government of India should institute an enquiry into the disturbing information given by the International Association for the Prevention of Blindness about the high incidence of trachoma in Indian regiments; that legislation regarding the inspection of the eyes of school-children be introduced at a very early date throughout British India and the States; that the machinery for the prevention of smallpox should be tightened up; that propaganda should be undertaken for the instruction of the uneducated concerning the prevention of blindness; and that medical departments for the treatment of the venereal diseases should be instituted, strengthened or extended, such being modelled, so far as possible, on those in existence in Great Britain.

OBITUARY

HELEN CHAMBERS, C.B.E., M.D. Lond.

Dr. Helen Chambers, whose enterprise and energy led to the foundation of the Marie Curie Hospital, died in Devonshire on July 21st after a long illness. Born in India, the only daughter of Frederick Chambers, I.C.S., Helen Chambers was educated privately in Guernsey and London and at Newnham. She entered the London (R.F.H.) School of Medicine for Women in 1898, and after a distinguished career as a student qualified in 1903 with a gold medal in forensic medicine and first class honours in obstetrics. She took the B.S., in 1904, and was at once made assistant pathologist and clinical pathologist to the Royal Free Hospital; Dr. A. G. Phear, one of the assistant physicians, being at that time pathologist to the hospital. Dr. Chambers's post was not a full time one and during the next few years she also held various research scholarships, notably the Mabel Webb research scholarship, and a newly founded scholarship in the cancer research department of the Middlesex Hospital, being one of the first of these scholars. Dr. Chambers took the M.D. in pathology in 1908, and in 1914 resigned from her post at the Royal Free Hospital to join the staff of the Military Hospital in Endell-street, which was staffed entirely by medical women, as pathologist. She worked there throughout the war and in 1920 received the C.B.E. in the first batch of those decorated with the Order of the British Empire. After the war Dr. Chambers became a full-time worker for the Medical Research Council at the Middlesex Hospital and the Marie Curie Hospital.

Her first publications were concerned with the thyroid gland, but as early as 1911 she began, in collaboration with Prof. S. Russ, the series of papers on different aspects of the biological effects of radium, for which she is chiefly known. Dr. Chambers became enthusiastic about the possibilities of radium therapy, especially for cancer of the cervix, and at a meeting of the London Association of the Medical Women's Federation in the spring of 1924 she induced the Association to appoint a committee to organise and carry out clinical research on this subject. A scheme was submitted to the Medical Research Council, and, with the coöperation of the British Empire Cancer Campaign, enough radium was received on loan to make a start and enough money to appoint a medical research officer as coördinating director. For three years the work was carried out at the three hospitals staffed by medical women in London and at the New Sussex Hospital for Women at Brighton, but the inconvenience of this plan became manifest, and in 1928 the radium research was concentrated at the Marie Curie Hospital at Fitzjohn-avenue with outstanding success.

Dr. Chambers never allowed her name to be personally associated with this or any other achievement—the only thing she cared about was that a "bit of work," to use her own phrase, should be done. Her anxiety was to persuade clinicians working with radium at the hospital to adopt the technique decided on, after extensive inquiry at home and abroad, without variation, so that the value of the method could be determined. This unification of treatment was made possible by the appointment of a medical research officer of experience and the success of the Marie Curie hospital in accumulating valuable records is due largely to the loyalty of the team to the ideals of the original research committee. Dr. Chambers had a rare combination of mental qualities, vision, zeal for controlled scientific research, and desire for social service. The outstanding features of her character were truth and loyalty. She was modest and retiring in disposition, but was always ready to come out of her shell of reserve to help those in physical or mental trouble. Her hobby was gardening, at which she was expert. She lived out of London, but attended regularly discussions at meetings of medical societies when subjects in which she was interested were under discussion; the loss of her critical judgment will be felt by all those concerned with the clinical applications of radium and X rays.

CHARLES GRAHAM GRANT, L.R.C.P., L.R.C.S. Edin., V.D.

THE death occurred on July 17th, of Dr. Graham Grant, doctor and barrister, who occupied until the beginning of the year the position of first clerk of arraigns at the Central Criminal Court, London.

Photograph by Lafayette

DR. GRANT

Charles Graham Grant was the son of Mr. Dundas-Grant, an Edinburgh advocate. He was born in 1864, received his professional education in the medical school of the University of Edinburgh, and qualified as L.R.C.S., L.R.C.P. Edin. in 1885. His varied medical work was all done in London, where he held at different times the posts of surgeon to the Poplar Hospital and medical officer to the Rotherhithe Tunnel works. He was also on the staff of the Tower Hamlets Dispensary and was medical officer to the Eastern District of the Post Office. He was surgeon to the H Division of the Metropolitan Police and for a period worked as clinical assistant at the Central London Throat and Ear Hospital. At different times also he served as surgeon on the following steamships: *City of Manchester*, *City of Oxford*, and *Anchises*. For a time he held a commission in the 24th Middlesex R.V., obtained the volunteer decoration, and at the time of the war was lieutenant-colonel, R.A.M.C. (T.F.). Much interested in medico-legal questions arising out of his work as police surgeon he wrote a manual on forensic medicine, and a small book, the "Diary of a Police Surgeon," which recorded his experiences in that capacity in an amusing and picturesque manner. In 1910, when he had been in practice for 25 years as a doctor, he was called to the Bar by Gray's Inn and was appointed Clerk of Arraigns in the Central Criminal Court, a position which he held for the next 25 years.

That is the bare outline of a life of great interest. Endowed with physical vigour, courage and strength of mind, Grant was able to perform the duties in his manifold fields of work with conscientiousness, undeterred by opposition or undue fear of offending.

Without aiming at high academical distinctions he maintained a solid standard of technical efficiency, directed by sound judgment and unruffled presence of mind. These qualities stood him in good stead as surgeon to the two large police areas where he was called at all hours to deal with cases of varying gravity. This long and observant experience inspired his book, entitled in its first edition "The Police Surgeon's Emergency Guide," a vade mecum that has been of service to many of his colleagues. His capacity for dealing with large bodies of men was displayed in his activities as surgeon to huge Post Office districts and medical officer to the Post Office Rifles in time of peace, as also to several large military camps during the war. When recommended for appointment to the post of Clerk of the Arraigns at the Old Bailey, the high official in whose hands the appointment lay stated that "he wanted as a coadjutor a man who when he said he had done a thing had certainly done it." In Grant he found his man. His devotion to the late Common Sergeant, Sir Henry Dickens, was most touching. It is no secret that during the later years of Sir Henry's life his work as judge was rendered difficult by an increasing dulness of hearing and that it would have been scarcely possible for him to have continued dispensing justice, for which he was so adapted (and did so acceptably) had it not been for the imperturbable support given by the younger man in interpreting evidence and statements which were often difficult to hear. For Graham Grant this work for his aged friend and principal superior was truly a labour of love.

Graham Grant had a highly attractive personality In his strenuous life he derived great enjoyment from the possession of many friends, and if they contributed to his happiness he in turn enhanced theirs. His high spirits made him a much-desired companion, and he will be greatly missed by many far beyond his family circle as well as by those to whom he was near and dear. His witticisms, his friendly repartees, his stories, Scotch as well as others, his songs, quaint and tuneful, his good-natured banter and his readiness to laugh over his own mishaps rather than over those of others, his ability and equanimity in games of skill will be recognised as among his social characteristics by those who had the pleasure of knowing him. He was a beloved and respected member of the Savage Club, who in large numbers testified to their respect for his memory by attending the funeral ceremony at Golders Green.

Dr. Graham Grant married Miss Jane Campbell Greig, of Perth, and leaves an only daughter, with three grandchildren, and though much sought after for social functions he had always strong domestic feelings. He occupied much of his spare time in household carpentering, at which he was an adept, and greatly enjoyed playing the piano for his young grandchildren to dance to.

JESSIE HANDYSIDE GELLATLY, M.D.

D.P.H. Edin.

THE death has occurred of Dr. Jessie Gellatly widely known for her official work in the county of Cambridge. She was born in 1884, the daughter of Mr. Stewart Gellatly, educated at the Medical College for Women, Edinburgh, and graduated M.B., Ch.B., at the university in 1906. She proceeded to the M.D. degree in 1910, and in the same year obtained the D.P.H. She was for a time house physician at the Leith Hospital, and filled the same post at the Hull Children's Hospital, after which she became resident medical officer at the Walthamstow Sanatorium, and later assistant medical officer to Messrs. Cadbury Bros. During the war she worked with the R.A.M.C. at Malta, Salonika, and in Serbia. At the conclusion of hostilities she was appointed assistant medical officer to the county of Cambridge, a post which she held for nearly 20 years and was holding at the time of her death. Here she proved an indefatigable worker. Her days were occupied with the inspection of schools, 130 in all, but she also gave in the evenings courses of lectures on school hygiene at the Homerton Teachers' Training College, Cambridge. An example of the way in which Dr. Gellatly interpreted her duties will be found in an article which she wrote in these columns (THE LANCET, Feb. 11th, 1933, p. 342) on milk consumption in rural households. Her experience of school medical inspection in her East Anglian area had shown her that the majority of children did not get milk as a beverage, tea of varying strength being commonly drunk from weaning, often a protracted period. In order to obtain evidence of the milk actually used in a number of households, Dr. Gellatly questioned 150 mothers attending school medical inspections, and set out in detail, with appropriate tables, figures showing that in the majority of the families the supply of milk was inadequate, while there was no compensating supply of other animal fats of good quality. The evidence supplied by Dr. Gellatly's investigation agreed with the recommendations to be found in the report of the Milk Commission; it was an excellent piece of work.

Miss M. M. Allan, principal of the Homerton Teachers' Training College, writes: "Dr. Gellatly's experience made her contribution to the training of young teachers extraordinarily valuable, for her daily contact with the problem of the maintenance of the health of school-children lent reality to her precepts. It was in this daily work in the schools that she made her most valuable contribution and formed some of her most lasting friendships. The school teachers in remote country districts found in her not only a wise consellor but a friend interested in their personal lives, and in their homes as well as their schools she received a warm welcome. Her work was difficult and of necessity lonely, demanding hard driving to remote districts in all weathers, but it was always her absorbing life interest and she carried it out with great independence of thought and wonderful courage. Her friends to whom her early death will prove an irreparable loss, are hoping to endow a child's cot at the local hospital in her memory."

MEDICAL OFFICERS IN INDUSTRY OVERSEAS.—A meeting was held at the Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine, on July 9th, to discuss the advisability of holding an annual conference to enable medical officers in industry overseas when on leave to meet together and review their various problems. Prof. W. W. Jameson, dean of the school, was in the chair. Medical officers present decided unanimously to accept the hospitality of the Ross Institute as their headquarters when on leave and to meet there for the discussion of professional matters. It was agreed that at first a conference lasting one day should be held in the beginning of July each year, invitations being issued through the medium of the British Medical Association and the various industrial associations. Any Government health officers home on leave from overseas would be invited to attend, and free discussion encouraged on any subject put forward by the medical officers present.

MEDICAL NEWS

University of Oxford

On July 20th the following degrees were conferred :—

D.M.—J. F. Brock, J. H. Hunt, C. W. Flemming, and C. R. Lane.

B.M.—J. R. Hollick, C. Hollins, N. Leitch, A. P. Meiklejohn, W. E. Henley, D. H. Hertz, W. R. Trotter, J. W. A. Turner, R. Bevan, E. M. Buzzard, C. F. Hamilton-Turner, P. C. Alexander, P. G. Burgess, H. Burton, W. J. C. Anstie, M. C. Chapman, J. C. Penton, D. F. G. Moir, and K. B. Dawson.

University of Cambridge

At recent examinations the following candidates were successful :

D.M.R.E.

Part I.—D. P. Bali, Alfred Pollitt, and I. G. Williams.

Part II.—D. P. Bali, J. L. Dobbie, T. P. Eustace, Leonard Freeman, A. H. Gibson, David Glass, P. R. Goodfellow, T. A. Green, B. T. Hooper, W. G. S. Hopkirk, A. S. Johnstone, Z. J. Joseph, A. H. Jowell, D. R. McPherson, Sambhunath Mukerjee, H. S. Rassim, and Beatrice M. Willmott.

University of Edinburgh

On July 17th the hon. degree of doctor of laws was conferred on Alfred Newton Richards, professor of pharmacology in the University of Pennsylvania. The following degrees and diplomas were also conferred :—

M.D.—A. A. F. Brown, J. A. Burgess, J. A. *Douglas, G. A. H. Gumley, T. B. Harvey, R. L. Langley, R. P. A. Macaulay, D. T. M'Donald, A. A. Miller, and A. A. Robertson.

* Commended for thesis.

Ph.D.—Heinz Schild and Hem Kanti Sinha (in absentia).

M.B., Ch.B.—H. M. Adam, J. D. Allan, John Allison, G. F. Anderson, K. C. Balfour, P. M. Barclay, Betty B. Barnetson, A. F. M. †Barron, Monoranjan Bhattacharjee, D. B. Black, J. B. Borthwick, Isaac Bortz, W. R. Brewer, A. K. Brooke, Stewart Brown, T. H. †Brown, R. T. Campbell, J. E. S. Carmichael, W. I. Chalmers, W. A. Coe, C. H. Comrie, W. R. M'K. Couper, J. M. Crawford, W. T. Cumming, H. A. Deverell, H. L. de Waal, J. M. Dick, Charles Donald, John Duncan, Jacobus du Toit-le Roux, Hermione K. S. Egerton, J. N. I. Emblin, M. R. †Ewing, Sigmund Falk, J. A. Farfor, Jean A. Forbes, J. W. Forbes, I. T. †Fraser, Henry Friedman, A. G. Gathorne-Hardy, Mary D. Gibson, James Gillan, I. C. Gilliland, J. C. R. †Greig, R. S. Hardie, J. P. Harger, M. S. Harvey, N. S. Hepburn, Thomas Hepburn, D. S. Hiddleston, Matthew Hunter, R. M. M. Hunter, J. J. M. Jacobs, John Jamieson, W. H. Kinstrie, T. A. Knowling, J. C. Lees, William Limont, M. G. Low, D. A. †Lowe, Abraham Lutton, Sydney Lyons, Allan M'Diarmid, V. P. M'Donagh, [illegible] Macdonald, A. M. M'Farlan, T. C. [illegible] A. M. Mackenzie, John MacKenzi [illegible] Macqueen, M. S. H. Makarim, O. A. S. Marais, E. G. L. Mark, W. H. C. Masters, J. S. Maxwell, F. O. Mell, Margaret MacK. Methven, G. R. Millar, Benjamin Miller, R. A. Miller, Robert [illegible] Niazi, J. C. Nicholason, A. A. Orr, [illegible] T. Paterson, H. O. [illegible] A. I. Pirie, J. E. Place, H. J. Pratap, [illegible] †Riley, A. J. A. Robertson, K. V. A. [illegible] gan, Leah Rosenbloom, J. B. Ross, C. [illegible] yness, John Scott, William Serle, William Simpson, Joan J. V. Spurway, Harry Stalker, C. P. Stevens, David Stevenson, N. F. Stocks, E. W. Stout, A. W. B. Strahan, Marian E. Sturrock, E. C. S. Talbot, A. N. Taylor, Alta F. Thompson, J. W. Thompson, C. H. Thomson, E. L. Thomson, G. M. Thomson, John Tillman, C. H. Tomlinson, G. F. Valentine, Wilhelmina J. Wagenmaker, R. M. Warren, J. D. Watt, A. [illegible] lkinson, N. V. Williams, C. M. Wilson, J [illegible] W. M'I. †Wilson, K. M. Wood, David [illegible]

† With honours.

D.P.H.—J. F. Caithness, G. W. Gale (in absentia), D. R. Huggins, D. J. Morrison, H. P. Tait, C. A. Green, Elspeth M. Warwick, and Henry Waters.

D.T.M. & H.—Charles Bowesman, A. B. Guild, and Alexander Scott.

Diploma in Psychiatry.—I. S. Campbell (in absentia), M. A. Nasr, and C. M. Ross.

Diploma in Radiology.—J. A. C. Fleming, J. P. M'Gibbon, A. G. G. Melville, and R. E. Verney.

The following awards of prizes were made :—

Cameron prize [illegible] ics to Julius Wagner-Jauregg, M.D., [illegible] psychiatry and neuropathology in th[illegible] in recognition of his discoveries regarding the malarial treatment of general paralysis ; Ettles scholarship and Leslie gold medal to M. R. Ewing M.B. ; Scottish Association for Medical Education of Women prize, to Frances M. H. Wilkinson, M.B. ; Murchison memorial scholarship in clinical medicine, W. M'I. Wilson, M.B. ; Mouat scholarship in the practice of physic, M. R. Ewing, M.B. ; Buchanan scholarship in midwifery and gynæcology, I. T. Fraser, M.B. ; James Scott scholarship in midwifery and gynæcology, T. H. Brown, M.B. ; Beaney prize in anatomy and surgery, T. H. Brown, M.B., and I. T. Fraser, M.B. ; Conan Doyle prize, J. N. I. Emblin, M.B. ; Annandale gold medal in clinical surgery, William Simpson, M.B. ; Royal Victoria Hospital tuberculosis trust gold medal, D. A. Lowe, M.B. ; Murdoch Brown silver medal in clinical medicine, A. F. M. Barron, M.B. ; Dorothy Gilfillan memorial prize, Margaret M'K. Methven, M.B. ; Wightman prize in clinical medicine, T. H. Brown, M.B. ; Pattison prize in clinical surgery, Alta F. [illegible] bert Jones prize in orthopædic surgery, [illegible] ; Syme surgical fellowship, J. J. M. [illegible] Barbour fellowship, N. G. Steere, [illegible] F. J. C. Herrald, M.B. ; Gunning [illegible] public health, C. A. Green, M.B. ; Gunning Victoria jubilee prize in medicine, I. M'Kenzie, M.B., and C. E. Van Rooyen, M.D.

An address was delivered to the new graduates by Prof. R. W. Johnstone, the promotor. See p. 215.

University of London

Mr. H. R. B. Fenn, lecturer in dental mechanics and prosthetics in the University of Liverpool, has been appointed as first holder of the chair of dental prosthetics at Guy's Hospital medical school ; Mr. James Whillis, F.R.C.S., lecturer in anatomy at the College of Medicine, Newcastle-on-Tyne, to the university readership in anatomy at the same school ; and Mr. E. P. Stibbe, senior demonstrator of anatomy at the London Hospital Medical College, to the university readership in anatomy at King's College.

Society of Apothecaries of London

At recent examinations the following candidates were successful :—

Surgery.—G. B. Barbour, Univ. of Camb. and Guy's Hosp.; A. H. El S. El Mahallawy, Roy. Coll., Edin. ; A. Morgan, Univ. of Manch. ; A. Ponder, Univ. of Camb. and Guy's Hosp. ; and K. G. Wrigley, Univ. of Sheff.

Medicine.—G. B. Barbour, Univ. of Camb. and Guy's Hosp.; H. N. Davis, Univ. of Oxf. and St. Bart.'s Hosp. ; E. M. Frankel, [illegible] E. T. Garthwaite, St. Bart.'s Hosp.; [illegible] of Oxf. and Guy's Hosp. ; J. B. Mair, [illegible] P. Pauli, Univ. of Brist. ; and G. N. [illegible] d West London Hosp.

[illegible]—G. B. Barbour, Univ. of Camb. and Guy's Hosp. ; H. N. Davis, Univ. of Oxf. and St. Bart.'s Hosp. ; E. M. Frankel, Westminster Hosp. ; J. B. Mair, Univ. of Glasg. ; and G. N. Rodgers, Bombay and West London Hosp.

Midwifery.—A. Aspinall, Univ. of Manch. ; A. N. Coondoo, Univ. of Durham ; G. R. Hopper, Univ. of Liverp. ; and F. W. Treadwell, Univ. of Birm.

The following candidates, having completed the final examination, are granted the diploma of the society, entitling them to practise medicine, surgery and midwifery :—

A. Aspinall, E. T. Garthwaite, A. H. El S. El Mahallawy, J. B. Mair, K. P. Pauli, A. Ponder, F. W. Treadwell, and K. G. Wrigley.

Royal College of Physicians of London

The College will be closed from Thursday, August 1st to Saturday, Sept. 14th.

Royal College of Physicians of Edinburgh

A quarterly meeting of the College was held on July 16th, with Dr. Edwin Bramwell, the president, in the chair. Dr. Sorab Kaikhoshru Engineer (Bombay) and Dr. Alexander Hay Rintoul (Crieff) were introduced and took their seats as fellows. Dr. Joseph Bryant (Khartoum), Dr. Hanna Barsoum (Alexandria, Egypt), Dr. Ratan Kumar Misra (Delhi, India) and Dr. Pritan Varialsing Karamchandani (Waziristan, India) were elected to the fellowship.

Royal College of Surgeons of Edinburgh

At a recent meeting of the College, with Dr. A. H. H. Sinclair, the president, in the chair, the following, who passed the requisite examinations, were admitted to fellowship :—

Sushil Kumar Nag Chowdhury, M.B. Calcutta ; Eyjolfur Jonsson, M.D. Manitoba ; Patrick Clarence Anderson, M.B. N.Z. ; Bernard Albert Armitage, L.R.C.P. Edin. ; Hamilton Bell, M.B. Belf. ; Andrew Anderson Bonar, M.B. Glasg. ; Hugh Benjamin Boucher, M.R.C.S. Eng. ; John Austen Percival Cameron, M.B. Edin. ; Eric Alan Davison, M.D. Belf. ; Wallace Milne Dennison, M.B. Glasg. ; Krishna Chintaman Gharpure, M.B. Bombay ; James Porter Heron, M.B. Edin. ; Benjamin Holden, M.Chir. Camb. ; John Muil Melvin, M.D. Glasg. ; James Stuart McGregor, M.D. Ontario ; Daniel John Percy Parker, M.B. Belf. ; Edgar Rowan Rankin, M.B. Witwatersrand ; and David Swartz, M.D. Manitoba.

Edinburgh Royal Infirmary

Lieut.-Colonel A. D. Stewart, C.I.E., I.M.S., has been appointed medical superintendent of the Royal Infirmary, Edinburgh, in succession to the late Colonel Thom. Colonel Stewart, who is 52 years of age and an Edinburgh graduate, is at present director of the All-India Institute of Hygiene and Public Health in Calcutta. He is likely to take up his new duties in the autumn.

A Deputation on Maternal Mortality

Last Tuesday Sir Kingsley Wood, the Minister of Health, received a deputation from the Standing Joint Committee of Industrial Women's Organisations. Dr. Esther Rickards said that no local authority was at present using to the full its powers to provide maternity services; and urged that the Ministry should compel them to provide satisfactory services. She referred to the standard of work of medical practitioners employed by local authorities, and suggested that the terms of service should be made more attractive and that only doctors with special obstetrical experience be employed. She also advocated the provision of a municipal service of midwifery. Alderman Rose Davies gave an account of the good results following the work of the Birthday Trust in the Rhondda, and asked for special financial assistance for distressed areas. Mrs. E. Barton stressed the importance of a proper provision of home-helps. She also took the view that a maternity patient should not be moved for at least 24 hours after her confinement, and that where a confinement took place in hospital she should not be sent home for fifteen days. Miss Mary Sutherland spoke of the need for postnatal clinics and for an inquiry into maternal morbidity, with particular reference to nutrition, and asked that local authorities should be urged to use more extensively their power to supply milk and meals. She also advocated legislation to secure the elimination of the untrained handywoman. Mrs. Ayrton Gould said that pregnancy commonly meant the loss of employment, and a woman who lost employment in this way was often unable to obtain either unemployment insurance benefit, or health insurance benefit. She hoped the Government would ratify the Washington Maternity Convention which would prevent the employment of women six weeks before and after confinement.

In his reply, Sir Kingsley Wood said that, comparing 1931 with 1934, there had been a steady increase in the provision of maternity services by local authorities; the number of antenatal clinics had increased by nearly 20 per cent., the number of women attending them by 23 per cent.—attendances reached nearly a million last year—the number of maternity beds by over 10 per cent., and the number of women admitted to them by 30 per cent. In addition the quality of maternity accommodation controlled by local authorities had been improved and most municipal hospitals aimed at retaining a patient for fourteen days after delivery. The majority of maternity and child welfare authorities now provided obstetric consultants, some 400 local authorities provided food or milk free or at cost price, and 133 provided home-helps. Action to stimulate the authorities of the areas where development was needed would be continued, but persuasion would as a rule do more than compulsion. The Ministry had been constantly pressing the need of improving and effecting services wherever necessary, and there never had been any question of their curtailment on financial grounds, even at the height of the financial crisis. On the contrary, special reference had been made to the need of their development, a point which was again emphasised last year when it was decided to institute special investigations into areas with persistently high rates of maternal mortality. Through the coöperation of doctors and midwives with the officers of the Ministry of Health information about fully three-quarters of the maternal deaths each year was obtained and forwarded to the Ministry. When the results of the present intensive investigation into maternal mortality had been received, it would be possible to decide the next steps to be taken in connexion with maternal morbidity. While there was no foundation at present for any definite statement on the relationship of nutrition to maternal mortality or morbidity special attention was being paid to this aspect of the problem. Proposals for an organised service of salaried midwives were receiving careful attention.

London (R.F.H.) School of Medicine for Women

The A. M. Bird post-graduate scholarship in pathology has been awarded to Dr. Margaret A. Jennings, and the Mabel Webb and A. M. Bird research scholarship to Dr. F. Charlotte Naish.

Princess Elizabeth of York Hospital

This institution at Shadwell, formerly known as the East London Hospital for Children and now called the Princess Elizabeth of York Hospital for Children, is being rebuilt at Banstead. The grounds were opened on July 22nd for subscribers to visit the site for the new hospital. An out-patient department will be run in the East End in conjunction with a hospital and convalescent home in the country.

Appointments

BEGG, N. D., M.D. Aberd., D.P.H., has been appointed Medical Superintendent of Infectious Diseases Hospital, Southend-on-Sea.

CUTLER, ROBERT, M.R.C.S. Eng., L.D.S., Hon. Dental Surgeon to Cheyne Hospital for Children, Chelsea.

DODDS, R. L., M.Ch. Belf., F.R.C.S. Eng., M.C.O.G., Hon. Out-patient Surgeon to the Samaritan Free Hospital for Women, London.

HUDSON, T. G. F., M.B., M.R.C.P. Lond., Resident Medical Officer of the General Infirmary, Salisbury.

HOLMES, J. M., M.B. Leeds, M.R.C.P. Lond., Hon. Physician to the Staffordshire General Infirmary.

PINCKNEY, C. P., M.B. Camb., M.R.C.P. Lond., Temporary Assistant Physician to St. George's Hospital.

REES, T. P., M.D., M.R.C.P. Lond., D.P.M., Medical Officer at the Croydon Mental Hospital.

SCOTT, J. A., M.D. Liverp., D.P.H., Medical Officer of Health for Fulham.

SCOTT, T. F. MCNAIR, M.R.C.P. Lond., Assistant Physician to St. George's Hospital.

SUGGIT, S. C., M.B. Lond., F.R.C.S., Hon. Assistant, Ear, Nose, and Throat Surgeon to the Children's Hospital, Hampstead.

WOOD, G. N., M.B. Camb., Hon. Assistant Physician to the Royal East Sussex Hospital, Hastings.

Certifying Surgeons under the Factory and Workshop Acts: Dr. N. J. BEE (Wainfleet, Lincoln); Dr. R. L. Walker (Lowestoft, Suffolk); Dr. J. W. BROMLEY (Bury St. Edmunds, Suffolk); Dr. A. L. WILLIAMS (Melbourne, Leicester); Dr. J. MATHESON (Rickmansworth, Hertford); Dr. W. P. GRACIE (Furnace, Argyll).

Vacancies

For further information refer to the advertisement columns

Accrington, Victoria Hospital.—H.S. £150.

Ashton-under-Lyne District Infirmary.—H.S. At rate of £150.

Bedford County Hospital.—Second H.S. At rate of £150.

Benenden, Kent, National Sanatorium.—H.P. At rate of £75.

Birmingham and Midland Eye Hospital.—H.S. At rate of £130.

Bolton Royal Infirmary.—H.S. £125.

Bradford Royal Infirmary.—H.S. At rate of £135.

Cambridgeshire County Council.—Asst. County M.O. £500.

Canterbury, Kent and Canterbury Hospital.—2 H.S.'s. Each at rate of £125.

Cardiff, Prince of Wales' Orthopædic Hospital.—Jun. H.S. At rate of £100.

Carlisle, Cumberland Infirmary.—H.P. Also Second H.S. Each at rate of £155.

Chester Royal Infirmary.—H.P. and two H.S.'s. Each £150.

Chichester, Royal West Sussex Hospital.—Sen. H.S. £175.

Chorley & District Hospital, Lancs.—H.S. At rate of £150.

Colchester, Essex County Hospital.—H.P. £150.

Derbyshire County Council.—Locum Asst. Maternity and Child Welfare M.O. At rate of £600.

Doncaster Royal Infirmary.—H.S. to Eye and Ear, Nose, and Throat Depts. £175.

Eastbourne, Princess Alice Hospital.—Res. H.S. £150.

East Ham Memorial Hospital, Shrewsbury Road, E.—H.P. At rate of £150.

Evelina Hospital for Sick Children, Southwark, S.E.—H.S. At rate of £120.

Gloucestershire Royal Infirmary &c.—H.S. At rate of £150.

Gravesend & North Kent Hospital.—Jun. H.S. At rate of £125.

Harrogate Royal Bath Hospital.—Res. M.O. £156.

Herefordshire C.C.—Asst. County M.O. and M.O.H. £750.

Hertford County Hospital.—H.P. At rate of £150.

Ilkley, Middleton-in-Wharfedale Sanatorium.—Sen. Asst. M.O. £450.

Institute of Medical Psychology, Malet Place, W.C.—Pædiatrecian.

Jersey General Hospital and Poor Law Infirmary.—Asst. Res M.O. At rate of £150.

Leicester Royal Infirmary.—Jun. Res. Anaesthetist. £125.

Liverpool City.—Res. Asst. M.O.'s for Special Hospitals. Each £200.

Liverpool Heart Hospital.—H.P. At rate of £100.

Liverpool, Mill-road Infirmary.—Sen Res. Asst. M.O. (Surgical). £350.

Liverpool University, Lectureship in Bacteriology.—£400

Macclesfield General Infirmary.—Second H.S. At rate of £150.

Manchester Ancoats Hospital.—Two H.S.'s. Each at rate of £100.

Manchester Ear Hospital, Grosvenor-square, All Saints.—H.S. At rate of £150.

Manchester Northern Hospital, Cheetham Hill-road.—Hon. Pathologist. £100. Also Bio-Chemist for Pathological Dept. £120.

Manchester Royal Infirmary.—Res. Clin. Pathologist. £150.

Miller General Hospital, Greenwich-road, S.E.—Anæsthetist. 52 guineas.

Newcastle-upon-Tyne, Hospital for Sick Children.—H.P. and H.S. Each at rate of £100.

Northampton County Mental Hospital, Berrywood.—Deputy Med. Supt. £550.

Norwich, Jenny Lind Hospital for Children.—Res. M.O. £120.

Nottingham Children's Hospital.—Res. H.S. At rate of £150.

Nottingham General Hospital.—H.S. For Ear, Nose and Throat Dept. At rate of £150.

Oswestry, Robert Jones and Agnes Hunt Orthopædic Hospital.—H.S. At rate of £200.

Preston, County Mental Hospital, Whittingham.—Deputy Med. Supt. £750.

Princess Beatrice Hospital, Earl's Court, S.W.—Hon. Clin. Asst.

Princess Elizabeth of York Hospital for Children, Shadwell, E.—Cas. O. Also H.S. Each at rate of £125.

Queen Mary's Hospital for the East End, E.—Cas. and Out Patient Officer. At the rate of £150.

Queen's Hospital for Children, Hackney-road, E.—H.S. and Cas. O. Each at rate of £100. Also Sen. Res. M.O. At rate of £200.

Reading, Royal Berkshire Hospital.—Cas. O. At rate of £125.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Rotherham Hospital.—Cas. H.S. £150.

St. Albans, Middlesex Colony for Mental Defectives, Harper Lane, Shenley.—Second Asst. M.O. £460.

St. Leonards-on-Sea, Buchanan Hospital.—Hon. Anæsthetist.

Sheffield, Children's Hospital.—H.S. At rate of £100.

Sheffield, Royal Infirmary.—Ophth. H.S. At rate of £120.

Stoke-on-Trent, Longton Hospital.—H.S. £160.

Sunderland Royal Infirmary.—H.P. £120.

Sutton and Cheam Hospital, Surrey.—Two Hon. Physicians.

Tunbridge Wells, Kent and Sussex Hospital.—H.S. £150.

Walsall, Manor Hospital.—Jun. Res. Asst. M.O. £150.

West Africa, St. Joseph's Hospital, Bolahun, Liberia.—M.O. £250.

Worksop, Victoria Hospital.—Sen. H.S. At rate of £150.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Llantrisant (Glamorgan), and Chester (Cheshire); latest date for receipt of applications July 30th; at Linlithgow, W. Lothian; applications before August 6th.

Births, Marriages, and Deaths

BIRTHS

BRUCE.—On July 16th, at Ranchi, India, the wife of Nigel Patrick Bruce, B.M. Oxon., of a daughter.

BUNYAN.—On July 18th, at Devonshire-place, the wife of John Bunyan, Surg. Lt. (D), R.N.V.R., Sheerness, of a son.

DREW.—On July 14th, the wife of Capt. W. R. M. Drew, R.A.M.C., of a son.

GALLAGHER.—On July 19th, the wife of C. E. Gallagher, M.R.C.S. Eng., Sidcup, Kent, of a daughter.

MCELDOWNEY.—On July 17th, at Carlton-road, S.W., the wife of A. P. McEldowney, M.R.C.S. Eng., of a daughter.

ORD.—On July 18th, at Knaresborough-place, S.W., the wife of G. E. Ord, M.B. Aberd., of a daughter.

PETERKIN.—On July 13th, at Hull, the wife of Dr. J. H. Stuart Peterkin, of a son.

SHEPPERD.—On July 16th, at Sutherland-avenue, W., the wife of Ronald Shepperd, L.D.S. R.C.S., of a daughter.

MARRIAGES

LEE—JACOBS.—On July 16th, at the Central Synagogue, Maurice Lee, F.R.C.S. Eng., of Wimpole-street, to Rosalie Doreen, elder daughter of Mr. Gaskell Jacobs, of Regent's Park.

MACDONALD—BOYLE.—On July 19th, at the Cathedral Church of St. Mary, Edinburgh, George Alexander Macdonald, M.B. Glasg., to Marguerite Louise Edwina, eldest daughter of Captain W. E. Boyle, A.E.C., Edinburgh.

PAYNE—WILLIAMS.—On July 20th, at St. Laurence Church, West Woodhay, Richard Vaughan Payne, M.B. Camb., to Zoë Mary Williams, only daughter of Mr. W. A. Williams, of West Woodhay.

ROBINSON—JACKAMAN.—On July 16th, at St. Giles' Church, Stoke Poges, Bucks, Allan Betham Robinson, M.B. Lond., to Evelyn Margaret, younger daughter of Mr. C. J. Jackaman, of Slough.

DEATHS

DE LISLE.—On July 14th, at Brunswick-square, Hove, Samuel Ernest de Lisle, L.R.C.P. Irel., many years Superintendent of Three Counties Asylum, aged 85.

FLETCHER-BARRETT.—On July 6th, suddenly, at Royat, France, William Fletcher-Barrett, M.B. Lond., of Cairo, Egypt.

GRANT.—On July 17th, Charles Graham Grant, L.R.C.P. Edin., V.D., Barrister-at-Law, Lieut.-Colonel R.A.M.C. (T.F.), late First Clerk of Arraigns, Central Criminal Court, aged 71.

HAYNES.—On July 16th, at Royal Naval Hospital, Chatham Surg.-Comdr. John Frederic Haynes, M.R.C.S. Eng., of Leamington Spa, aged 44.

MILLER.—On July 17th, at Clive-court, W., Arthur Alan Miller, M.D. Durh.

SHAW.—On July 18th, at a nursing home, Inverness, John Shaw, M.B. Aberd., of Grantown-on-Spey, formerly of Denmark-hill, S.E., aged 57 years.

TREDINNICK.—On July 20th, in London, Ernest Tredinnick, M.R.C.S. Eng., L.R.C.P. Edin., formerly of Craven Arms, Shropshire, aged 84.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Medical Diary

SOCIETIES

INTERNATIONAL NEUROLOGICAL CONGRESS.

MONDAY, July 29th.—9.30 A.M. (University College, Gower-street, W.C.), opening. 10 A.M., Discussion: The Epilepsies—their Ætiology, Pathogenesis, and Treatment.

TUESDAY.—9.30 A.M., Discussion: The Physiology and Pathology of the Cerebro-spinal Fluid.

WEDNESDAY, July 31st.—9 P.M. (B.M.A. House, Tavistock-square, W.C.), Prof. O. Foerster: The Motor Cortex in Man in the Light of Hughlings Jackson's Doctrines. (Hughlings Jackson memorial lecture.)

THURSDAY, August 1st.—9.30 A.M., Discussion: The Functions of the Frontal Lobe.

FRIDAY.—9.30 A.M., Discussion: The Hypothalamus and the Central Representation of the Autonomic System.

Notes, Comments, and Abstracts

A LADY COMPANION

Dr. Kathleen Vaughan writes:—"I have just made the acquaintance of Jinny, a chimpanzee of 18 months old, and brought up from birth by an Englishwoman, who lives near Daru in West Africa. Jinny seems to understand everything, is obedient and clean, and can fetch things when told. After having her hair trimmed she tries to use the scissors and comb for herself. She is affectionate and kisses her friends the dog and cat. She can wash her own face, cleans the floor with a damp duster, can open the door and gets on to a tricycle but likes to turn the pedals with her hands. A day or two ago she took a tablecloth, which had been hung up to dry, off the line, and brought it into the house, just before rain came—but we think this was a coincidence! When her mistress told her to give the dog half her biscuit she did so, but when he wanted her piece she put it in her mouth, showed it to him and then dodged behind the leg of the table, ducking her head when he came near. This went on for a long time: finally she let him take it from her mouth. She has been taught she must never take food and can only have it when it is given to her.

"Can your readers suggest a career for such a civilised little person, for here comes the sad part of the story. The owner has a young baby and cannot look after both charges. Jinny loves to help push the pram and kisses the back of the baby's head, but will probably be jealous of it. She must be sold. What is the best thing to do for her? Would Elstree take her, or a zoo where she could act as governess to young chimpanzees?

It has been ascertained that there are as many chimpanzees at Regent's Park as are wanted. Jinny is in Alderney at present with her owner, Mrs. G. Basham, to whom inquiries may be addressed."

THE RESTORATION OF THE CRYSTAL PALACE

ON Thursday evening, July 18th, H.R.H. The Duke of Kent visited the Crystal Palace to see the recently restored architectural courts. Many of these and the statuary, having been there for 80 years, had fallen into dilapidation, and in that state merited the general neglect received. Now, under restoration, the Crystal Palace has claims on public attention, apart from the well-known displays of fireworks. It is the only building in England possessing a whole series of courts, which illustrate architecture through the ages, and are built on a scale large enough to give a definitely realistic impression of ancient, mediæval, and renaissance art. The chief feature of the restoration is a full-size replica of the courtyard of a Pompeian house. This had been closed to the public for 25 years, but two years ago intensive restoration work was started by the staff of the Palace and the mural colouring and mosaic paving have been restored to their former brilliance. The Crystal Palace should again be numbered with the popular pleasure resorts of London.

ADDRESSES AND ORIGINAL ARTICLES

INFECTION AND ITS CONTROL IN CHILDREN'S WARDS *

BY E. H. R. HARRIES, M.D. Lond.

MEDICAL SUPERINTENDENT, NORTH-EASTERN HOSPITAL (LONDON COUNTY COUNCIL)

LECTURE II.

UPPER respiratory tract infections are ordinarily transmitted by droplet spray, but in the measles wards which were referred to in my first lecture there was no evidence of the occurrence of post-admission broncho-pneumonia amongst children adjacent to those admitted with that complication—there being 12 feet of wall space between cot-centres. Such cases as occurred, 39 amongst 1464 admissions of measles patients up to the age of five years, were quite haphazard as regards spatial distribution in the ward.

Upper respiratory tract infections differ greatly in their degree of infectivity. Virus diseases are the most highly infective and are very much more readily transmitted either by droplet spray or upon the hands of attendants than are bacterial infections. This is due in part, no doubt, to the minute size of the viral bodies and in part to the fact that some of the virus diseases are characterised, in their early stages, by sneezing and coughing. In some experiments upon the droplet dissemination of virus diseases Colvin [1] using bacteriophage as an indicator because it has numerous points of resemblance to viruses, found that sneezing was a hundred times more infective than coughing. The bacteriophage was demonstrated only in the droplets and thus was dispersed in exactly the same way as bacterial respiratory tract infections. That virus diseases may be most highly infective during the prodromal stages is particularly well recognised in the case of the common cold, measles, and chicken-pox.

1. *The Common Cold.*—Long, Bliss, and Carpenter [2] showed that the common cold may be infective to apes late in the incubation stage. They think it is improbable that masking of the infected person is a complete protection against dissemination and point out the possibility of the contamination of hands which, after having been scrubbed, have unconsciously been allowed to touch the face. Bliss and Long [3] showed that it was necessary for an infected person merely to prepare the food in the kitchen, taking no part in its distribution to the chimpanzees, this being carried out with the strictest aseptic precautions by others, to infect several of the animals with severe common colds.

2. *Measles and Chicken-pox.*—Considerable knowledge has been acquired as to the most infective phases and modes of dissemination of these two diseases as the result of the observations of those who have practised in fever hospitals the various methods of segregation founded upon the work of Grancher and of Hutinel in the children's hospitals of Paris with such later improvements of technique as were devised at the Pasteur Hospital opened in 1900.[4] [5] Grancher [6] in 1889, at the Hôpital des Enfants Malades, devised movable screens and adopted an antiseptic technique, and Hutinel,[6] in 1894, at the Enfants Assistés, contrived boxes or cubicles combined with antisepsis and asepsis in order to diminish the dangers which arose from the dissemination of infection amongst children aggregated in open wards. The conditions which they endeavoured to guard against were not the specific fevers but the "infections banales" of the respiratory and gastro-intestinal tracts.

Those who planned fever hospitals in the past failed to provide adequate isolation accommodation. Thus, fever hospital administrators, from the sheer necessity of accommodating those patients who, for one reason or another, it was unsafe to admit to ordinary wards, have been amongst the earliest to adopt the principles and practice of Grancher and Hutinel.

Thirty years ago, Gordon Pugh [7] by subdivision of three existing wards at the North-Eastern Hospital, first reproduced Hutinel's cubicles in this country and instituted a technique of aseptic nursing which is still carried out in the same cubicles which, however, are shortly to be replaced by new structures. Pugh found that measles and chicken-pox could not be nursed in these cubicles without danger of spread and this remains the case. In 1934 a total of 831 patients were admitted to the 34 cubicles contained in the three wards. Of these, 638 were suffering from infective conditions and 193 from non-infective conditions. Only 2 patients initiated cross-infection. They were each admitted in the incubation stage of chicken-pox and from each one case of that disease arose in another cubicle in the same ward.

Goodall [8] in 1910 divided a ward at the Eastern Hospital into completely separate chambers closely similar to those at the Pasteur Hospital. Even complete structural separation and an aseptic technique will not always prevent the transference of measles and chicken-pox from one chamber to another. A breach of technique may result in personal contact of patients or manual transference by the staff. Chapin [9] in his classical work on "The Sources and Modes of Infection" stressed the importance of personal contact and the manual transmission of infection and the relative unimportance of aerial spread. His work lent great support at the time to the experiments of Rundle of the Liverpool City Hospital, Fazakerley, who was evolving the system known as *bed isolation*. Crookshank,[10] it must be noted, had immediately prior to the appearance of Chapin's book introduced a similar system upon a small scale at the Barnes Isolation Hospital.

Bed Isolation

Bed isolation assumes an "invisible barrier" created by spacing and aseptic technique around *each* patient in the ward as distinct from the "barrier nursing" of one or more patients in the ward. Barrier nursing was introduced by J. Biernacki at the Plaistow Fever Hospital about 1908. Coloured bands or cords indicated in scarlet fever wards those patients who were to be regarded as potentially infective to other patients in the ward and who were, therefore, to be nursed "in barrier" with strict asepsis. Rundle and Burton [11] and Rundle [12] showed that patients suffering from a variety of infective and non-infective conditions might be nursed with a notable freedom from cross-infection in the same open ward providing that the "invisible barrier" surrounding each patient was scrupulously maintained. Thomson and Price [13] arranged a bed-isolation ward, the existing spacing of 15 *feet* between bed-centres being adhered to. They concluded that under the conditions obtaining in the ward, diphtheria and scarlet fever definitely, and mumps and rubella probably, were not air-borne. Measles, they thought, was air-borne early in the disease, and chicken-pox, intensely infective and air-borne in its early stages, was not infective after the third day from onset. Thomson [14] found that on two occasions in the same ward, under the same conditions, chicken-pox arose in patients separated by the whole length of the ward (90 feet) from the primary source; on three occasions when the distance was half the length of the ward, and on ten when the distance from the source was shorter. He believed that aerial transmission was the most likely mode of spread.

---

* The Milroy lectures for 1935, delivered before the Royal College of Physicians of London.

Harries,[15] as the result of his experience in two bed-isolation wards in Birmingham, found that with neither 9 feet nor 12 feet of wall space could patients admitted in the prodromal stages of measles or chicken-pox be nursed without danger of spread. Between adjacent cots aerial transmission was possible, but over longer distances infection was much more likely to be conveyed by attendants. It was extremely unlikely, for example, that the virus of measles spread aerially in an oblique direction across the ward in a dosage sufficient to bring about simultaneous attacks in three children in adjacent cots upon the opposite side of the ward. Aerial transmission was an unlikely explanation of the mode of spread of the virus of chicken-pox through the whole length of a ward and a lobby to a corner cot in an adjacent division of the ward, intermediate susceptibles remaining uninfected.[15] (1924.)

Bacterial infections of the upper respiratory tract are much less infective than virus diseases. Glover [16] showed the conditions of spacing in sleeping quarters under which the meningococcus might be disseminated. Eagleton [17] found that in ordinary sleep this organism was not carried more than 5 feet. During violent coughing it may be spread three times this distance, a much shorter distance, he added, than in the case of many other organisms. A single act of sneezing or coughing may be sufficient to infect with the virus of measles a child in the next cot, but much more massive or more frequently repeated doses are necessary for the effective transmission of bacterial infections. It is notable how rarely whooping-cough, when introduced inadvertently in its infective phase, is disseminated in open wards with adequate bed-spacing, even when the patient is not nursed in in barrier. Thomson and Price concluded that the evidence of the aerial transmission of whooping-cough in their bed-isolation ward was not definite.

Experience with the cough-plate method of diagnosis shows that the plate must be held within 4 or 5 inches of the child's mouth when it is in the act of coughing, and even then the Bordet-Gengou bacillus is recoverable only in a proportion of cases. Kendrick and Elderling [18] obtained positive cultures from 78 per cent. to 84 per cent. of 207 clinically diagnosed cases of whooping-cough during the first three weeks of the disease; 39 per cent. in the fourth week and 0 per cent. in the sixth week. On the other hand, Macdonald and Macdonald [19] by the actual implantation upon the nasal and faucial mucosa of approximately 140 bacilli produced typical attacks of whooping-cough in two non-immune boys who had volunteered for the experiment.

Close contact, or the actual introduction of the causal organisms into the nasopharynx upon fingers or implements is necessary for the transmission of diptheria or scarlet fever. With 12 feet of space between cot-centres it is very unlikely that effective aerial transmission of bacterial infections occurs. It is doubtful whether it is possible for an enfeebled child suffering from broncho-pneumonia by repeated acts of coughing to produce a "velocity of infection," Dudley's term,[20] sufficient to infect in other than minimal doses the upper respiratory tract of another child 12 feet distant from the source and, a fortiori, of a child more remotely situated.

I believe that the post-admission complications which occurred in the measles wards referred to earlier in so far as they were not autogenous, resulted from relatively gross infection of the upper respiratory tract by means other than droplet spray. The grounds for this belief are that when children with bacterial upper respiratory tract infections are nursed in wards with identical bed-spacing, the additional safeguard of an aseptic technique being applied to each patient in the ward, spread of infection does not occur.

Adult Carriers

Of the three common viral infections discussed—viz., the common cold, measles, and chicken-pox—the last two may be ruled out as being introduced by adult convalescent carriers. Nearly all adults are immune to these two diseases as the result of an attack in childhood, and chronic carriers are unknown. Temporary contact infection of the nasopharynx, hair, hands, and clothing of adults may result in the transference of these diseases from one ward to another, and be the explanation of some outbreaks otherwise unexplainable. The common cold and similar "influenzal" conditions are undoubtedly introduced and disseminated by adults who enter children's wards in an infective condition. Crosbie [21] found that the masking of the staff in infant wards protected the patients from catarrhal infection, with the result that enteritis almost disappeared from those wards.

Spence [22] observed that the incidence of scarlet fever in his children's wards declined markedly when visiting was limited. Fever hospitals are exempt from mass visitations of parents. Visiting is strictly limited as to occasion and duration. Hooded gowns and a prescribed distance from the bed are insisted upon. Hands and face are washed before leaving the institution. Under such conditions it is unlikely that visitors to fever hospital wards play any important part in the transference in or out of the institution of purely bacterial infections, such as diphtheria or scarlet fever, but that they may introduce infections of the type of the common cold is more than probable.

The question of staff carriers is important. Joe [23] remarks that in isolation chambers nursing technique only operates to prevent infection between patient and patient, and the possibility of occasional staff carriers (of scarlet fever) must be borne in mind. He adds that the only methods of eliminating cross-infection from this source would be to adopt continuous masking or rigid bacteriological standards of freedom from infection, measures attended by insuperable practical difficulties.

Christie [24] found that nurses in pneumonia pavilions became temporary contact carriers of the pneumococcus but apparently without danger to themselves or others. My colleagues, Begg and Mair,[25] report that of a series of new entrants to the nursing staff at the North-Eastern Hospital during the autumn of 1934 who were swabbed before commencing duty for the first time in the wards, 56 per cent. harboured hæmolytic streptococci in the nose or throat, but in none were the organisms present in pure culture. If the nasopharynx was healthy, probationers, although harbouring the organisms at the time of beginning duty in the wards, soon lost them. If, on the other and, there was an abnormal or unhealthy condition f the nasopharynx, they tended not only to retain emolytic streptococci but to become profuse rriers or to develop streptococcal tonsillitis. No ntrant harboured diphtheria bacilli, and only one bsequently became a temporary (immune) carrier hile nursing diphtheria patients.

Cultures from the nose and throat of 173 nurses orking in various wards proved positive for the æmolytic streptococcus in 88 instances. Of these, he colonies were sparse in 54, numerous in 31, and in ure culture in 3 instances only. More than half he cultures showing numerous colonies and the only hree pure ultures were erived from urses attending carlet fever patients. Of nurses with healthy throats, 61·5 per cent. *returned negative results*, compared with 16·6 per cent. in the case of those with unhealthy nasopharyngeal mucosa. Clearly it is the nurse in the latter category who is potentially in danger herself and most likely to be a source of danger to others. Dr. V. D. Allison, of the Ministry of Health, kindly typed the strains recovered. They comprised 38 strains of the hæmolytic streptococcus, 19 of which fell into those frequently associated with tonsillitis, puerperal fever, and other hæmolytic streptococcal infections.

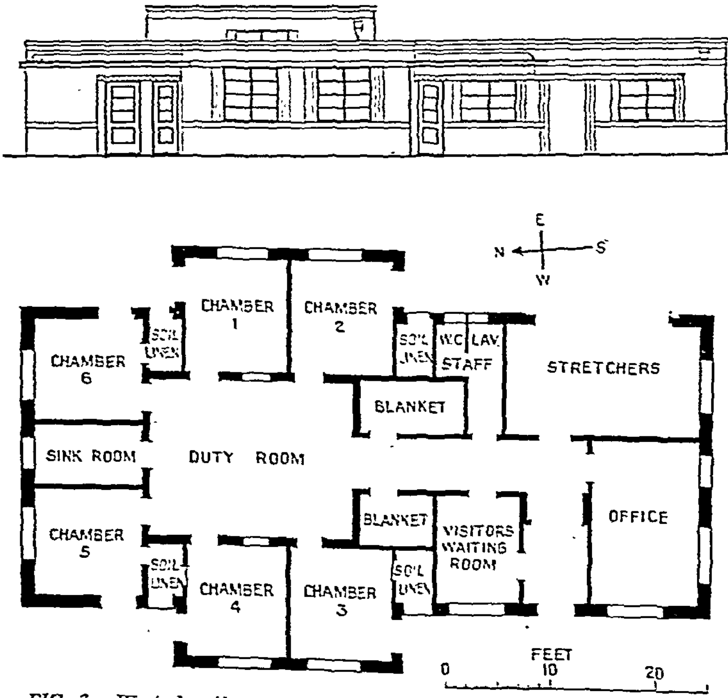

FIG. 3.—West elevation and ground-floor plan of new receiving block at the North-Eastern Hospital.

Control of Ward Infections

It is not feasible in the general children's hospital to eliminate entirely the danger of the waiting-room and casualty-room. The receiving-rooms of fever hospitals, to which children are brought by ambulance for confirmation of diagnosis and allocation to the wards, may be similarly dangerous, unless properly planned. When fever hospitals received, as such, only three notifiable infectious diseases—viz., diphtheria, scarlet fever, and enteric fever—small-pox being then, as now, admitted to separate hospitals, the single-chambers provided for each of these three diseases may have been adequate, but with the enlargement of the clinical field they are no longer so. In some provincial fever hospitals this fact has been recognised for many years, and receiving-rooms dispensed with, patients being examined, and allocated to wards, in the ambulance itself, a plan which has much to recommend it.

A receiving-room shortly to be erected at the North-Eastern Hospital will provide six separate chambers, *each* of which can be entered from the exterior and also from a central interior duty-room. The plan of this receiving-room (Fig. 3) and succeeding plans, are reproduced by permission of the medical officer and the clerk to the London County Council.

Preliminary Quarantine

Mackenzie[26] notes the tendency of children's hospitals in England to isolate young children for at least 48 hours *after admission* and, where accommodation allows, for several days. That preliminary quarantine, even for a few days, does operate to reduce the number of children admitted to the wards in an infective or *potentially infective condition* is the experience of Crosbie[21] at the Alder Hey Children's Hospital. Amongst 7746 admissions, 1276 children who were known contacts or who showed suspicious symptoms, were admitted to isolation blocks *for an average* period of 6 days. Of those so isolated, 35 per *cent.* developed some infectious disease. Preliminary quarantine, however, to be really effective, must be imposed upon all entrants for a period of three weeks, in order to cover the longest incubation period of the common fevers. Such a period is impossible as a general measure for hospitals receiving children suffering from acute illnesses; the institution would be disorganised. Nor, in such institutions, is it possible to impose quarantine, even for a limited period, upon *every* child admitted. (The circumstances of the long-stay hospital which receives tuberculous or rheumatic children differ entirely, for here universal and adequate quarantine may be practicable.)

Preliminary quarantine imposed even upon a limited scale must make great demands upon the available isolation accommodation, which is being increasingly used in both children's and fever hospitals for the segregation of patients suffering from infections other than the exanthemata.

Isolation Accommodation

A committee of the American Academy of Pediatrics[27] analysed the conditions under which communicable diseases of all types were nursed in 35 representative children's hospitals in the United States of America. The large number of these institutions which segregate in cubicles patients with respiratory tract infections, other than the specific fevers, is noteworthy. The recognition by fever hospital *authorities* that children with such conditions as broncho-peneumonia and otitis *media* constitute

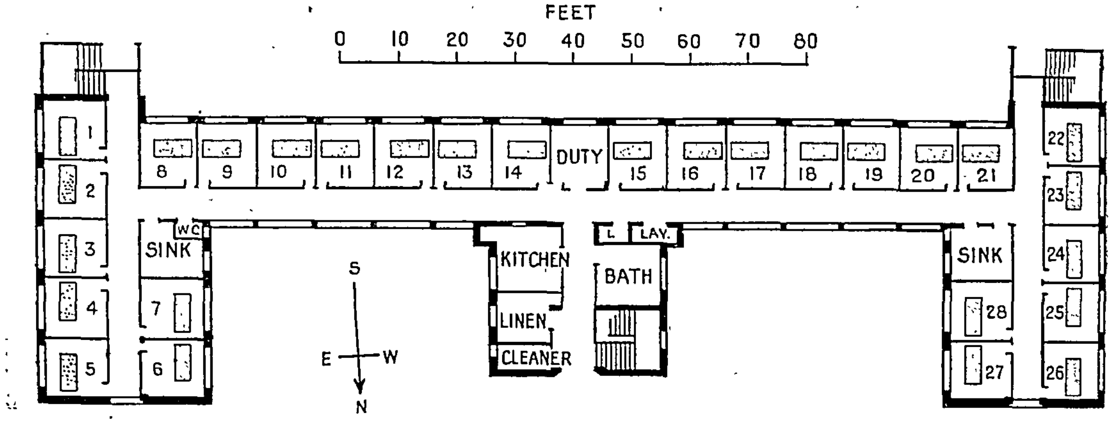

FIG. 4.—Ground-floor plan of one of two new isolation blocks. The stippled rectangles represent beds.

potential sources of infection when nursed in ordinary wards, unless indeed all are nursed in barrier, which is not generally practicable, has as a necessary sequel the provision of greatly increased isolation accommodation. In the fever hospitals of the London County Council this increased accommodation is being provided by the erection of two-storied blocks containing in each floor a large number of separate chambers.

In the plan (Fig. 4) of a floor of one of two such blocks, shortly to be erected at the North-Eastern Hospital, it will be seen that 28 separate chambers are provided. The two blocks will thus contain 112 single chambers or "wardlets."

It is neither feasible nor desirable to nurse every child in a chamber; the majority must and should be admitted to larger wards. Hence it is desirable to consider the conditions which should obtain in these wards in order that the dissemination of extraneous infection of any type inadvertently introduced may be reduced to a minimum.

Seventy years ago, Murchison[28] advocated for fever patients an allowance of 2000 cubic feet of air space, but he recognised that, however perfect the ventilation, "small-pox and scarlet fever will spread among persons not protected."

Although adequate ventilation is essential, the most important factor is not cubic space but space between bed-centres. The minimum standard of the Ministry of Health for fever hospitals is 9 feet between the edges of the beds, 12 feet between bed-centres, and 144 square feet of floor space. This standard is maintained in the infectious diseases hospitals of the London County Council and in newly constructed wards in the provinces—e.g., at Birmingham and Coventry. Those who have had experience of fever wards where this standard was not attained in normal periods and encroached upon in epidemic periods by the intercalation of additional beds, can be in no doubt as to its necessity. Overcrowded scarlet fever wards, for example, result in a greatly increased incidence of extraneous complications, such as, rhinitis and impetigo. An overcrowded ward implies overworked nurses who cannot perform routine nursing duties satisfactorily, while any attempt at barrier nursing which necessitates not only adequate spacing but rigorous aseptic precautions, cannot do other than create a false sense of security.

Mackenzie, in his survey, notes that the standards at present adopted for the accommodation of sick children in general or children's hospitals are 7 feet between bed-centres, a superficial area of 77 feet, and 847 cubic feet of air space. But it must be added that in children's wards, recently built or contemplated, the allowance of space between cot-centres is being steadily increased.

Liberal provision of small wards adjacent to the main ward and partial subdivision of the main ward itself by means of glass screens are outstanding features of recent design in both children's and fever hospitals. As representing this type the plan (Fig. 5) of one of a number of new wards shortly to be erected at the North-Eastern Hospital is reproduced. Within the subdivisions the beds are arranged in parallel, adjacent cot-heads being separated by a glass screen 7 feet high. Parallel spacing of beds is admittedly on trial. Various objections, such as difficulty of supervision have been urged. During the last measles epidemic the cots were arranged in parallel in a ward of the simplest "temporary" type at the North-Eastern Hospital. Twelve feet of space between

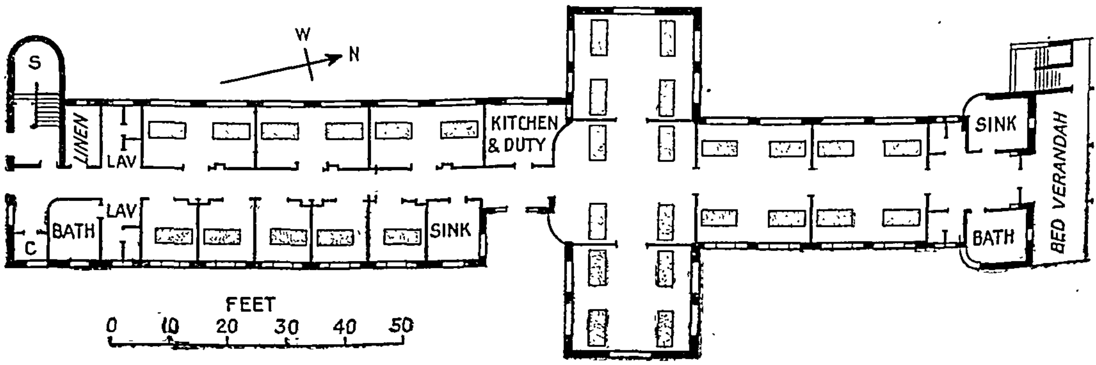

FIG. 5.—First-floor plan of a new ward block.

ot-heads was maintained, but, s the photographs (Figs. 6 nd 7) show, no glass screen ivided one patient from the ext. The results of the xperiment were entirely avourable. Draughts from he open windows were avoided nd supervision presented no ifficulties. The children were quite happy, making friends not with the next in line, but with those on the opposite side of the ward. The nurses were pleased with the arrangement. Owing to the fact that some 3 feet of space intervened between the wall of the ward and the side of the cot, access for nursing and cleansing purposes was easy.

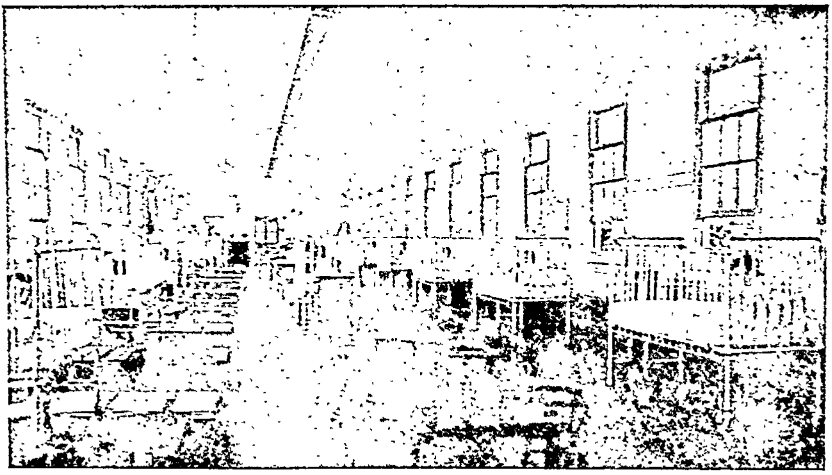

FIG. 6.—General view of ward.

The large open undivided ward which implies many children at risk from extraneous infections of one kind or another must be considered as obsolete. But such wards must nevertheless remain for some time to come in many institutions. Rebuilding is only possible as and when financial resources permit.

The Spread of Infection

It is wise to assume that in children's wards any one child is a potential source of infection to any other. Therefore, if it is necessary when complete physical barriers separate one child from the next, as in isolation chambers, to adopt in addition a technique of aseptic nursing for each child whether itself deemed infective or not, still more does this become desirable in the open ward where no physical barriers exist. It is true that under the present conditions of staffing this practice is ordinarily impossible of attainment, but it is nevertheless the ideal which should be kept in view.

As Nabarro and Signy[29] point out, nurses who feed children should not be those who attend to their stools. This subdivision of duties has been in force for several years at, for example, the Birmingham Babies' Hospital. But no nurse should give any sort of attention to a child without scrubbing her hands before proceeding to the next patient. Even if sufficient numbers of nurses were available this procedure is unlikely to be carried out unless there is ample provision of surgeon's basins with running water. The mere provision of numerous nurses and of facilities for hand-washing is useless unless the fundamental importance of surgical cleanliness of the hands is not only realised but ingrained in the nursing staff. It is unreasonable to expect a girl to acquire within a few weeks those principles of aseptic nursing, the application of which may be literally vital in wards containing young children.

In all wards, whether barrier nursing is employed or not, convalescent children are a source of trouble. In barrier wards, they may, unless constantly supervised, break the barrier and become infected. In ordinary wards convalescent children are also at risk of infection or reinfection amongst themselves. Schlesinger[30] has emphasised the danger of spread of epidemic throat infections amongst rheumatic children when up and about.

Reinfection is particularly likely to occur when convalescent diphtheria or streptococcal carriers are aggregated in open wards for the treatment of the carrier state. Even long series of negative swabbings may be interrupted by the return of a positive result. This may be due to true intermittency of the carrier state but, under the circumstances, is quite as likely to be due to re-infection. Thus Anderson and his co-workers[31] have been able to isolate the gravis strain of the diphtheria bacillus from convalescent carriers who hitherto had only harboured the mitis strain; which is strong presumptive evidence of reinfection.

Many diphtheria carriers believed to be intermittent are in reality reinfected contact carriers.[32] Some years ago I tried masking diphtheria convalescents with a view to avoiding reinfection. The results, as seen in earlier clearance, appeared to be promising, but practical difficulties such as the speedy damping and soiling of the mask with resulting excoriation

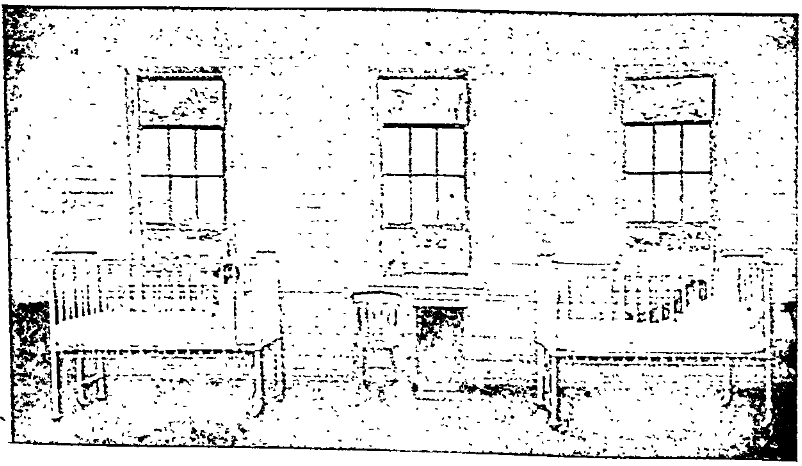

FIG. 7.—Beds spaced in parallel.

of the skin, and the necessity for its removal during meal times, led to the abandonment of the practice. The only satisfactory way to accommodate diphtheria or hæmolytic streptococcal carriers whilst their treatment, operative or otherwise, is in progress is in single or very small wards. In open wards carriers are frequently artifacts.

The limitation of the *spread* of a specific infection following its inadvertent introduction into a children's ward necessitates :—

1. Prompt detection and segregation of the probable primary source of infection.
2. Determination, so far as possible, of the number of immunes and non-immunes to that particular infection amongst the remaining children in the ward.
3. Protection of the non-immunes by such specific prophylactic measures as are available or feasible.

The primary source of infection may be obvious ; a child is inadvertently admitted in the incubation stage of, for example, measles or chicken-pox, and in due course develops a clinical attack. But if the time which has elapsed between admission and the development of the attack exceeds the longest incubation period of the particular disease, the primary source is either a child who has suffered an abortive and unrecognised attack, the "missed" case, or a carrier amongst patients or staff.

Amongst the viral infections atypical attacks of mumps such as solitary sublingual or submaxillary forms are easily missed ; and the occasional neurotropism of the virus of chicken-pox is now generally accepted. The occurrence of a ward outbreak of chicken-pox following the appearance of herpes zoster has time and again been within my own experience.

In the case of the specific bacterial diseases, the primary source may again be obvious, but if not, owing to the availability of bacteriological methods for the detection of carriers can usually be traced.

Determination of the number of immunes and non-immunes remaining may be impossible or may be effected with considerable accuracy. It may be necessary to rely upon the history of previous attack as indicating immunity, but the degree of reliability of such histories varies much with the disease. It is not great in the case of measles owing to the extent to which this disease is confused with rubella. It is considerable in the case of whooping-cough ; the attack has not only been unmistakable but of such duration as to impress it upon the mother's memory. In two conditions the evidence of immunity may be read upon the skin. The cicatrices of variola or vaccinia and of varicella are, as a rule, characteristic in distribution and appearance.

In diphtheria and scarlet fever direct methods for the determination of immunity are available in the Schick and Dick tests, but they must always be combined with a search for carriers, since it is amongst the immunes that the chronic carrier will be found.

Passive Immunisation

Passive immunisation is of proved value against three of the common specific infections—diphtheria, scarlet fever, and measles—and of doubtful or at least of unproved value against mumps and chicken-pox. The great advantage of passive immunisation is the rapidity with which it is brought about. Its disadvantages are two : the temporary nature of the protection afforded and the possibility, where an animal serum is the vehicle of provoking or initiating by the injection of foreign protein, either anaphylactic or serum phenomena.

Against two only of the diseases mentioned above —diphtheria and scarlet fever—are animal antitoxic sera employed ; human serum has perforce to be injected in the case of the others. Within recent years the process of concentration or refinement of specific animal antisera, by reducing their protein content, has resulted in a notable diminution of serum troubles of any kind.

Diphtheria antitoxin has been available for prophylaxis for forty years, since it was in 1894 that Roux and Martin announced its production. The prophylactic dose which consists usually of from 1000 to 2000 units protects on the average for three weeks.

Scarlet fever antitoxin, as such, resulted from the work of the Dicks and of Dochez, and has been in use for about ten years. The prophylactic dosage of concentrated serum ranges, as a rule, from 5 to 10 c.cm. The duration of the protection afforded, although varying with different batches of serum which cannot be standardised with the accuracy which is possible in the case of diphtheria antitoxin, ranges between 10 and 14 days.

Scarlet fever antitoxin is now widely employed for prophylaxis in both fever hospitals and children's hospitals. Recently, J. G. Fitzgerald [33] has reported that at the Toronto Hospital for Sick Children all patients who are shown to be Dick-positive reactors at the time of admission receive a prophylactic dose of scarlet fever antitoxin. As a result of the practice, the incidence of scarlet fever in that institution is stated to be only one-tenth of what it was prior to its introduction.

MEASLES

The value of the seroprophylaxis of measles by the injection of human convalescent or adult-immune serum is now generally recognised. Convalescent serum has been in routine use for several years in large fever hospitals. Amongst the earliest to use it in the wards of children's hospitals were Nabarro and Signy.[34]

Convalescent measles serum is difficult to obtain in adequate supply. Hence it is fortunate that the value of adult-immune serum has been proved. It was first employed, so far as this country is concerned, in the wards of the Birmingham City Hospital in 1929.[35] The results of subsequent trials upon a large scale in London have been set out in a report [36] of the medical officer of the London County Council. Although inferior to convalescent serum for prevention it has a value for attenuation as great as that of convalescent serum. The dosage of measles serum must be regarded as tentative. Different batches of pooled serum vary considerably in their protective value.

CHICKEN-POX

Various attempts have been made to protect exposed susceptible children against chicken-pox by the injection of convalescent serum. Blackfan, Peters, and Conroy [37] were successful as was Weech.[38] Gordon and Meader [39] also claimed a considerable measure of success. Schmidt,[40] on the other hand, failed. Gunn,[41] more recently, found that pooled varicella serum had a definite protective value—inferior, however, to that of convalscent measles serum in the same doses. Amies [42] has identified in the vesicles of chicken-pox elementary bodies similar to the Paschen bodies in small-pox and has demonstrated specific agglutinins in the blood of convalescents. He thinks it may be possible by means of the agglutination reactions to detect those sera which have a high antibody content, thus making selection instead of pooling possible. It is sincerely to be hoped that this, indeed, may be feasible, and that chicken-pox, the one common specific infection, which so far virtually defies all efforts at control, may at length become amenable to seroprophylaxis.

MUMPS

Similar suggestive results have been obtained in the seroprophylaxis of mumps by Hess,[43] Debré,[44] Regan,[45] Teissier,[46] de Lavergne and Florentin,[47] and by Gunn,[48] who thinks that the method is deserving of further trial.

Active Immunisation

In long-stay hospitals for children active immunisation against diphtheria of both staff and patients is practised increasingly often. So far as short and intermediate stay hospitals are concerned, active immunisation is ordinarily only applicable as an internal measure of control to the staff. Vaccination against small-pox, which is still insisted upon in most hospitals, and the inoculation with T.A.B. of those nurses who are attending to patients suffering from enteric group infections are well-established procedures.

Active immunisation of the staffs of fever hospitals against diphtheria was first introduced some 14 or 15 years ago at the Edinburgh [49] and Birmingham City Hospitals,[50] and is now adopted for the protection of the staffs of large numbers of hospitals of all types. Active immunisation against scarlet fever was also introduced several years ago in the same two fever hospitals [51] and, although not so generally practised, its value is undoubted.[52]

There is no evidence that active immunisation increases the carrier-rate amongst nurses. Although chronic carriers are always immune, the occurrence and persistence of the carrier state amongst the staff as the result of contact infections is, as was shown earlier in this lecture, closely connected with the existence of abnormal nasopharyngeal mucosa.

Conclusion

In these lectures the overwhelming importance of the upper respiratory tract as an actual or potential focus of infection has been emphasised. The problem of control of infection in children's wards virtually centres upon the upper respiratory tract.

Well ventilated, adequately spaced and subdivided wards with ample provision of isolation accommodation are essential. But no degree of architectural skill, no medical administrative measures, and no elaboration of technique can prevent entirely the transference of infection by human agencies.

The best-laid schemes may fail unless, in addition, the personnel is numerically and technically adequate to cope with the special dangers of infection which must inevitably attend the aggregation of children in hospital.†

DERMATITIS FROM DYED HAIR, FURS, AND FABRICS

By John T. Ingram, M.D., M.R.C.P. Lond.

PHYSICIAN IN CHARGE OF THE SKIN DEPARTMENT, GENERAL INFIRMARY, LEEDS; LECTURER ON DISEASES OF THE SKIN, UNIVERSITY OF LEEDS

One of the recognised varieties of eczematous dermatitis is that in which a skin develops a specific hypersensitiveness towards one or more external agents which in themselves are harmless to the normal individual. The result of such idiosyncrasy differs in no way from ordinary constitutional eczematous dermatitis or from dermatitis due to non-specific hypersensitiveness and provoked by such forms of irritation as exposure, change of temperature, soaps, water, friction, or household chemicals.

Dye dermatoses are of this specific character. The reactions in themselves are not recognisable as forms of dye dermatitis—as was suggested in a recent medico-legal case—but the site of the eruption suggests hair, fur, or fabric dye as a probable cause. No final opinion can be given on these cases without investigation, and for this purpose the patch-test gives reliable and absolute evidence.

This test should be used as a routine in all cases of eczematous dermatitis in which specific sensitiveness to some external agent is suspected. A little of the suspected excitant—or more often a portion of lint moistened with a solution of the substance—is applied to the skin of the patient for 24 hours (or less if an active reaction is obvious). If the eczematous dermatitis is due to the substance of the patch-test, a positive eczematous reaction is seen at the time of removal of the test or within 24–48 hours, though it is wise to keep the subject under observation for longer than this if a negative result is to be accepted. If the lint becomes dry it should be moistened to ensure intimate contact. This is especially important in the case of dyed-fabric tests.

Experience has, however, taught me to use no more than one drop of a 1 per cent. solution of para-phenylenediamine in patch-testing a case of suspected hair or fur-dye dermatitis. If this is done the procedure will not be embarrassing.

INCIDENCE OF HYPERSENSITIVENESS TO DYESTUFFS

Hair and fur dyes.—In dye dermatitis it is commonly para- or meta-phenylenediamine, or allied substances, or one of their oxidation products, which is the external agent involved. In a previous communication the results of an investigation of the incidence of hypersensitiveness to para- and meta-phenylenediamine and their oxidation products were reported.[1] In this investigation 1000 patients were patch-tested with solutions of 1 per cent. para-phenylenediamine and with 1 per cent. and 5 per cent. solutions of meta-phenylenediamine, and it was found that about 4 per cent. of the patients showed evidence of hypersensitiveness, which was manifest at periods of 1–24 days after removal of the test. In the discussion upon these results the desirability of investigating a number of these cases by *repeated* test applications of the external agent was indicated and part of the purpose of the present paper is to describe an inquiry of this kind.

In all 45 patients were tested by repeated applications of a solution of 1 per cent. para-phenylenediamine. Of the 45, 15 were females and 30 males, of ages varying between eighteen and forty-five; 20 of these were normal subjects, 4 were known to be eczematous, 1 had suffered from urticaria and the remainder had lupus vulgaris. As in the previous investigation, the presence of some para-phenylenediamine in the patch-tests after the completion of the investigation, and the presence of Bandrowsky's base (indicated by blackening of patch-test and skin) showed that these, as well as intermediate oxidation products, had of necessity repeatedly come into contact with the skin of the patient investigated.

These patients, over 20 of whom had been patch-tested to para- and meta-phenylenediamine and were among the negative results in the previous investigation, were patch-tested with 1 per cent. para-phenylenediamine solution, applied daily to the upper arm by means of a linen and elastic cuff, for a period of approximately 12 hours, by day, and removed at night time over the course of a month. At intervals of a week the patch-test was resaturated with 1 per cent. para-phenylenediamine solution. In effect, the subjects investigated had a patch-test of para-phenylenediamine solution applied daily for 28–31 consecutive days, the tests, of course, being reapplied to the same sites each day. At the end of this period the applications were stopped and the subjects were kept under observation for a period of a month. In no case was any positive result recorded.

It was argued, in the previous communication,[1] that fur and hair-dye dermatitis are the result of idiosyncrasy in the patient, a view which is probably accepted by all dermatologists and in support of which there is abundant evidence. It would seem from this present investigation, that in addition to the fact that a very small proportion of normal subjects exhibit idiosyncrasy to these particular chemicals, hypersensitiveness is not readily provoked by the kind of repeated contact with these substances which ordinarily takes place.

Fabric dyes.—The very low incidence of dermatitis from dyed fabrics is an indication of the rarity of hypersensitiveness to these common dyestuffs.[2] On several occasions a dyed fabric which has provoked a single case of dermatitis has been patch-tested upon 100 normal subjects with negative results, and it has been customary in the skin department at the Leeds General Infirmary to use such fabrics as controls in making routine patch-tests. In no case has a positive result been obtained except in the case of the original sufferer.

DIAGNOSIS OF DYE DERMATITIS

In considering an eczematous eruption the points which suggest a dye dermatitis are the site, often an associated œdema, and the relationship of the onset to dyeing of hair, or wearing of a dyed fur or fabric. Sometimes the staining of the skin from dye dissolved out of a garment by sweat suggests this possibility, but it will be readily realised that none of these factors provide absolute criteria and usually the original diagnosis can be no more than tentative, to be confirmed or denied and corrected by subsequent observation and investigation.

Œdema, particularly affecting the eyes, is an important and common but not a constant accompaniment of dermatitis arising from the use of hair dyes and fur dyes. It is only rarely seen in any considerable degree in cases of fabric-dye dermatitis. In the latter the precise localisation of the eruption is much more valuable than in fur and hair-dye cases where localisation closely corresponds to that of seborrhœic eruptions and eruptions due to exposure to external irritation.

In the case of dyed frocks the limitation of the eruption to the upper trunk and arms where contact has occurred is often striking, the lower margins being defined by the upper limit of the petticoat and the skin lying under the shoulder straps escaping by an exact line of demarcation (Fig. 2). Another localisation of value and importance here is that of the axillary eruption which leaves the dome of the axilla clear, since contact occurs only below the axilla and round the axillary folds, whereas seborrhœic dermatoses show their maximum affection at the axillary apex (Figs. 3 and 4).

When eruptions are provoked by dyed socks, stockings, hat-bands, wristlets, &c., the limitations are usually suggestive. In the case of dermatitis from dyed shirts localisation may be less precise if that garment is worn next the skin, but the axillary eruption often gives the clue.

These affections commonly follow a first or early contact with the offending hair-dye, fur or garment, though it is well recognised that the development of specific hypersensitiveness may be considerably delayed. A patient may submit to the process of hair dyeing repeatedly over the course of many years before she becomes intolerant. It should be stressed, however, that there is no evidence to suggest that a reaction may be delayed longer than a certain period, probably a month, after contact has ceased.

[1] Ingram, Brit. Jour. Derm. and Syph., 1932, xliv., 422.

Killick, E. M., and Ingram, J. T., THE LANCET, 1933, i., 77.

Dermatitis provoked by the phenylenediamines is more severe and acute than fabric-dye dermatitis and may give rise to secondary eruptions shortly after the onset of the initial affection or while that is subsiding. These are itching or eczematous dermatitis about the flexor aspects and flexures of the limbs, hands, and feet, or a toxic, morbilliform erythema with peripheral distribution, often widespread and distressing. It is difficult to determine whether these are manifestations of a general reactive eczematous sensitiveness, the skin acting as a single whole organ, or whether they are from absorption of inflammatory products of the initial eruption, or from absorption of the actual substances which have provoked the dermatitis. The latter seems probable since secondary manifestations may be present when the original disturbance has been relatively mild.

It is usual for patients suffering from dye dermatitis to recover readily when the cause is removed, but it must be recognised that the reaction may, for constitutional reasons, persist for months or years. Under such circumstances it is usually probable that if the dye had not done so, some other hazard would have provoked the constitutional breakdown or manifestations other than dermatological would have arisen.

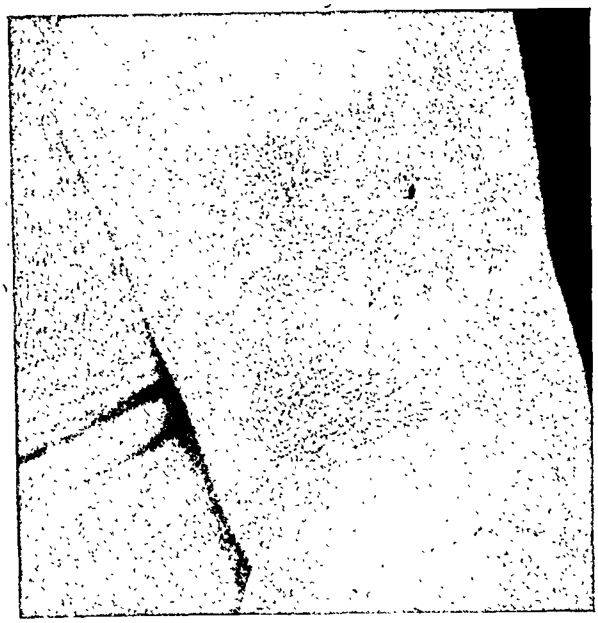

FIG. 1.—Positive patch-test reaction to 1 per cent. paraphenylenediamine in a case of dermatitis from dyed fur coat worn for four years.

Though a tentative diagnosis of dye dermatitis is commonly made, subsequent investigation and observation show that dye dermatitis of any type is rare. In a series of 8000 out-patients in the skin department at hospital I have seen no more than 16 cases of dermatitis due to dyestuffs. These figures do not include the occasional cases seen in dye-workers when numerous other factors enter into the ætiology, and it is rarely possible to attribute dermatitis to contact with dyestuffs alone. Of these 16 cases 6 were attributable to hair dyes, 3 to fur dyes, and 7 to fabric dyes, including 2 cases of dermatitis from the wearing of dyed khaki shirts. In a series of 4000 private cases 14 cases of dye dermatitis have been seen, 6 due to hair dyes, 4 to fur dyes, and 4 to fabric dyes. These figures may be relatively high because cases of medico-legal interest are specially directed to the dermatologist for an opinion; on the other hand it is probable that fewer cases are overlooked than in the rush of hospital practice.

Taking these figures together, 30 cases of dye dermatitis have been seen in a series of 12,000 skin cases, 12 from hair dyes, 7 from fur dyes, and 11 from fabric dyes.

Consideration of the private cases, to which greater care can be devoted, shows some points of interest and emphasises the constitutional eczematous background in these as in all dermatitis cases. In all but 2 cases there was definite evidence of nervous instability, marked in 4 cases and manifest in 1 case in a recent history of nervous breakdown. In many cases the phase of instability could be ascribed to recent experiences. In 2 cases the condition was associated with shock and was provoked by the wearing of black garments for mourning, though in neither case was the bereavement the only shock. One patient had been seen with lichen planus twelve months before her attack of hair-dye dermatitis and another was subject to urticaria. Two of the cases of hair-dye dermatitis were at other times subject to fabric-dye dermatitis though one case only was seen in eruption.

The frequency of the relationship of dye dermatitis to domestic, environmental, and psychological disturbances suggests that the reaction may be regarded upon occasion as in the nature of an associated conditioned reflex reaction. These points, while not disproving the specific nature of the sensitiveness to dyestuffs, suggest that a heightened general physiological sensitiveness, especially with nervous and dermatological manifestations, predisposes to specific sensitiveness.

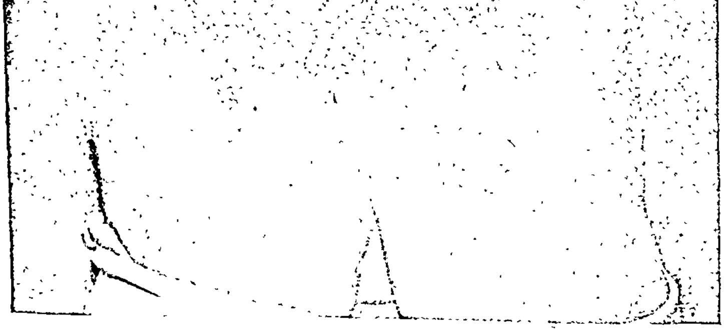

FIG. 2.—Distribution of fabric-dye dermatitis showing the eruption limited below by the upper edge of petticoat and not affecting the shoulder-strap areas.

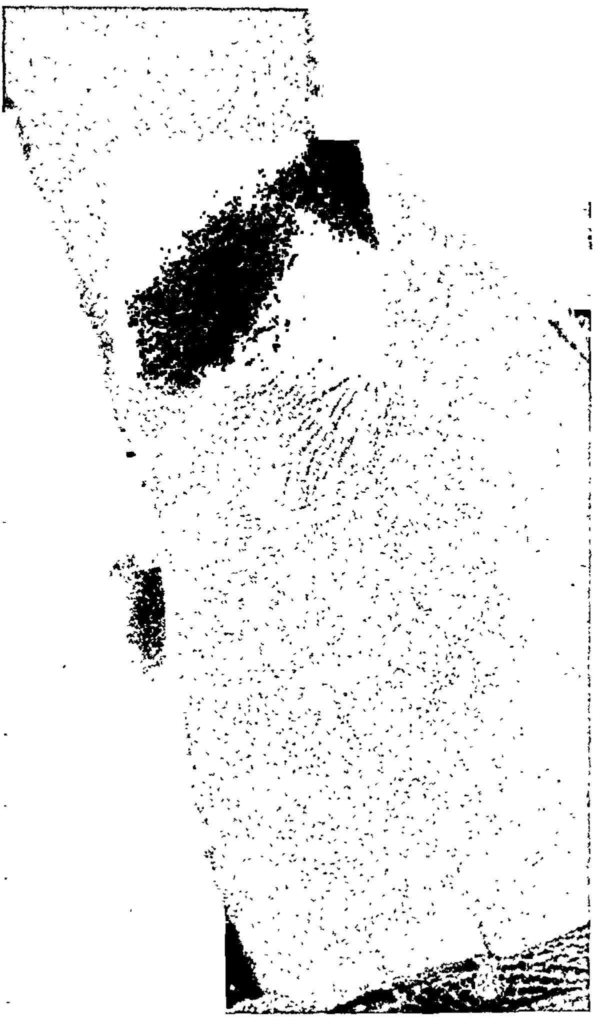

FIG. 3.—Axillary eruption in fabric-dye dermatitis (Case 4).

ILLUSTRATIVE CASES

The following cases illustrate some of the points to which reference has been made above.

CASE 1.—Mrs. A., aged 37, seen on Nov. 22nd, 1934, complained of an irritable eruption about the chin and neck of one month's duration. There was a scaling erythema of the sides and front of the neck and of the muzzle, limited above by the nasolabial folds. This was shown to be due to the wearing of a mole-coloured fur collar, black-tipped, and obviously brush-dyed. There was a marked positive patch-test reaction to the fur and to one drop of a 1 per cent. solution of para-phenylenediamine. The patient had not suspected this association. The fur was the only one owned by her. It had been bought two years previously, in September, 1932, had been worn each winter and had been worn this Autumn for about three months. It would be interesting to hear the judgment in such a case should the patient bring an action for damages.

CASE 2.—Miss B., a nervous patient aged 35, had used a hair dye (containing the phenylenediamines) three weeks before her visit. The following day she developed an eruption of her scalp which in three days was an acute, œdematous dermatitis of the whole head, face, and neck, with swelling of eyes, intense itching and malaise, and her hair was cut off. Within the following week a morbilliform erythematous eruption developed on the hands, forearms, thighs, eczematous in the flexures of elbows and axillæ. The trunk and feet itched and showed faint mottling. Two months later she was seen with an acute pompholyx immediately following the dyeing of a cushion.

CASE 3.—Mrs. C., aged 37, was seen with acute œdematous dermatitis of head, face, and neck, flexures of elbows and knees, breasts, buttocks, and feet. This had immediately followed dyeing of the hair (phenylenediamine), the patient having only had her hair dyed once, five years previously. Patch-tests to both para- and meta-phenylenediamine were embarrassingly positive. The patient was a highly neurotic Jewess, under aural and ophthalmic surgeons for nasal trouble and headaches. Some years previously she had an ovary removed. She had also been attending an out-patient physician for treatment of asthma but she gave no history of previous skin troubles.

CASE 4.—Mrs. D., aged 32, complained of attacks of itching, redness and swelling of the armpits over the course of three months, associated with the wearing of a green frock which had been dyed black. There was the acute, eczematous, saddle-shaped dermatitis of axillæ shown in Fig. 3, which completely avoided the apex of the axilla. A patch-test of the dress applied on July 29th, 1932, gave an acute positive reaction on July 30th, which was still recognisable a fortnight later. The patient perspired freely, and it is to be noted that the eruption only occurred at the sites of moist contact.

CASE 5.—Mrs. E., aged 46, presented an itching, scaling, erythematous eruption of upper chest and arms of four months' duration. The skin protected by the under-garments was not affected, but the patient had not suspected the cause of her eruption. She was therefore patch-tested against all her frocks—two flowered fabrics, one check, one light grey, and one black. She gave a marked positive reaction to the black fabric only and the eruption cleared following removal of the cause.

Black, brown, and khaki fabrics appear to be the commonest causes of this type of dermatitis.

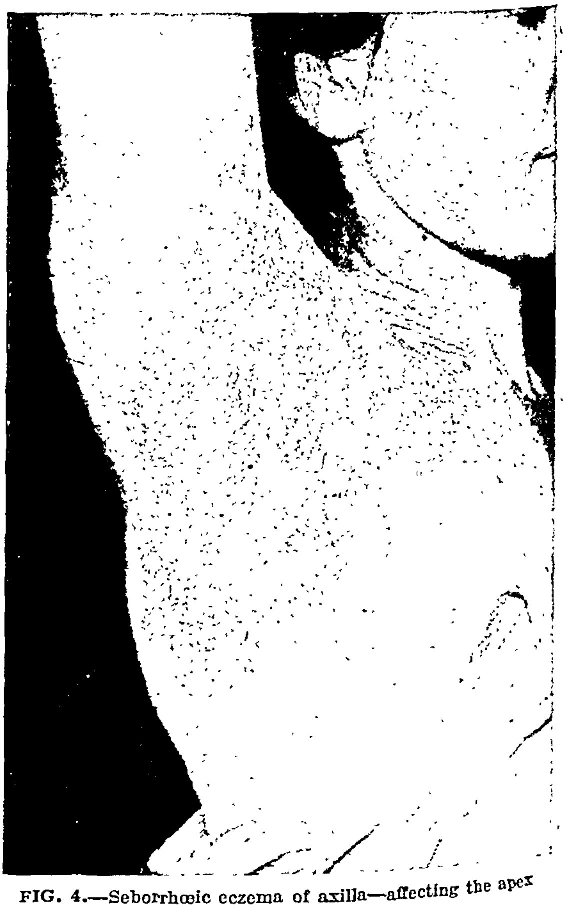

FIG. 4.—Seborrhœic eczema of axilla—affecting the apex

SUMMARY AND CONCLUSIONS

No clinician could seriously suggest that the reaction of hair or fur-dye dermatitis or of fabric-dye dermatitis was not due to idiosyncrasy. The clinical evidence is support of this view is abundant, while the alternative suggestion that such conditions are due to an irritant substance (using the term irritant in the ordinary sense to mean something irritant to the majority of normal persons) serves only for purposes of legal argument and cannot stand up to serious clinical investigation. The workers in the dye industries are not subject to more dermatological troubles than other trades—whereas the irritant theory would make this industry an impossibility in practice.

The patient suffering from hair-dye dermatitis has often had exactly similar treatment on other occasions, and the same treatment is being carried out without ill-effect upon hundreds of other people. A patch-test in such a patient will produce an embarrassingly positive reaction, while the same patch-test in other subjects gives a negative result. The sufferer from fur-dye dermatitis can give her fur to a hundred other persons to wear and they will suffer no harm. The patient with fabric-dye dermatitis can be similarly generous with her offending dress without fear of provoking dermatitis and she is wearing material treated with dyestuffs which are in contact with the skins of thousands of individuals and are serving their legitimate purposes without injury.

Dye dermatitis, like plant dermatitis, or light dermatitis, and an infinite variety of other sensitisation reactions, is exactly analogous to urticaria produced by sensitisation to eggs, or to asthma resulting from sensitisation to roses. Most medical authorities probably appreciate this, if they do not always preach it; but it would mean the saving of enormous sums of money, of invaluable time and of much unnecessary ill-health if legal authorities could be persuaded to accept it. It is probably too much to hope for this until there has been a complete revision of the Workman's Compensation Act, in so far as it is related to dermatitis arising from "irritant dusts and liquids," and it is probably true that our terminology, often misleading in its dogmatism, prevents patient, doctor, and lawyer from viewing the subject in true perspective. The terms eczema, dermatitis, and eczematous dermatitis have been used as interchangeable terms in this paper for it is fundamental that the conception of any distinction between eczema and dermatitis should be broken down.

PROCTALGIA FUGAX

A LITTLE KNOWN FORM OF PAIN IN THE RECTUM

By Th. E. Hess Thaysen, M.D.

CHIEF PHYSICIAN, ST. ELISABETH'S HOSPITAL, COPENHAGEN

Last summer I was consulted by a colleague about pain in the rectal region, of which, although a diligent reader, he was unable to find any description in the literature to which he has access. It thus acquired a mysterious character, which added to his anxiety.

Case 1.—The doctor referred to, who was 59 years of age, had always been in good health apart from the ordinary diseases of childhood. He had lived in St. Croix for a couple of years, but had never suffered from any tropical disease. He was able to eat all kinds of food and had no trouble with his bowels unless he drank much coffee, when the motions were rather loose. For three or four years he had suffered from quite unexpected pain without any suggestion of periodicity, which he referred to the rectum, always in the same place a little above the sphincter ani, but how far up he could not tell. The pain was not radiating; it appeared quite suddenly at intervals of days or months when least expected, generally in the daytime. It only occasionally awakened him in the night. It was described as gnawing pain, slight at first but increasing steadily to a considerable degree of severity, so that he had to lie down. He felt ill during the attack, but did not know whether he became pale. It disappeared quickly leaving behind no ill-effects whatever apart from some lassitude. The attacks were said to last for about two minutes.

I found nothing abnormal at the usual examination; a rectal exploration proved that everything was normal except that the sphincter ani was rather tight, which was due probably to the discomfort of the examination.

I had to confess to my colleague that I myself had not seen any report of these attacks of pain, but I was able to inform him that they were well known to me and gave him a description of them which he said corresponded with his own attacks. I have met with this pain a dozen times or so in my practice, but as I do not keep a card index of the diseases of my patients I can find the notes of only two cases treated during the last few years.

Case 2.—A man, 47 years of age, previously healthy, was treated at St. Elisabeth's Hospital in 1928 for gastric ulcer (melæna). He had since had periods with slight symptoms of ulcer and some tendency to constipation. For at least ten years—that is, several years before the gastro-intestinal trouble occurred—he had been subject to quite unprovoked attacks of pain at intervals of some days or several months, which he referred to the rectum a little above the anus. The pain was always in the same place, it was not radiating but had a gnawing character and in the course of a few minutes became extremely violent, after which it quickly subsided. At the height of the attacks he often felt a kind of pulsation in the rectum. The pain was so violent that he could do nothing during the attack, but had to keep absolutely still or throw himself on to a sofa or chair. He became pale and cold, perspired, and at the same time was conscious of a tight sensation in the precordium or epigastrium which made him gasp for breath and gave him the impression that he was gravely ill. At first he always had only one attack, but later, two, following closely upon one another. They occurred generally in the morning, more rarely later in the day and were then less violent.

When the attack was over he felt perfectly well, though a little tired. The pain had no connexion whatever with meals or the state of the bowels, and was only occasionally associated with hard motions. He had consulted several doctors about these attacks, but examination never revealed anything abnormal—no hæmorrhoids or fissures; nor was I able to demonstrate any place in the sigmoid, rectum, or anal canal from which the pain could arise. Rectoscopy showed nothing abnormal. The attacks of pain had not prevented him from working and had become less frequent in the last few years. The patient is the director of a big firm.

Case 3.—A married lady, 39 years of age. Treated in 1934 at St. Elisabeth's Hospital for bronchial asthma, bronchitis, and myalgia dorsi. For several years she had typical bronchial asthma as well as myalgic pains in back and chest. Lately, somewhat depressed and inclined to crying. No dyspepsia; bowels open daily, spontaneously. Rectovaginal examination revealed a retroflexed uterus and a slightly enlarged cystic right ovary.

For at least five or six years the patient is said to have suffered from sudden and inexplicable pain which she referred to a point about 10 cm. up in the rectum, definitely not to the anal ring, and always in the same place. The pain was convulsive in nature and increased steadily to a maximum, when she felt violent tension in the entire pelvic region. She grew pale and perspired and also felt a dragging sensation in the precordium or the upper part of the epigastrium which left her breathless; she often fainted in an attack. The attacks were soon over, but she could not tell even approximately how long they lasted. She would say: "I do not know, but I suffer terribly while they last." On another occasion she said that they lasted at least ten minutes. The attacks occurred very irregularly at intervals of days or several months; the last severe attack was experienced about eighteen months previously, since when she had only had abortive attacks. She felt well after the attacks apart from lassitude, often very pronounced. She could not suggest any reason whatever for the occurrence of the attacks; at any rate they have no connexion at all with the state of her bowels.

Examination of the alimentary canal showed nothing abnormal apart from some atrophy of the skin round the anus; she had been suffering for a few years from pruritus ani. There were no hæmorrhoids or fissures. Rectal exploration and rectoscopy (30 cm.) disclosed nothing abnormal. She thought that the pain was located round the sigmoid flexure. It was impossible to find any point from which the attacks could have started. The spinal fluid was normal. Wassermann reaction negative.

In my experience these attacks of pain occur both in men and women. All my patients have been adults, and except two they all suffered from some gastro-intestinal disease for which they sought my help.

FEATURES OF THE ATTACKS

The characteristic features of these attacks are :—

1. Their quite unaccountable occurrence when the patient is in perfect health. They appear at very irregular intervals at all times of the day and night.

2. Their spontaneous disappearance without leaving behind any ill-effects except a quickly passing lassitude; more important still, they are not followed by disturbances of the intestinal function (constipation or diarrhœa).

3. The localisation of the pain in the rectal region above the sphincter ani, always at the same place in the same patient, but varying somewhat in different patients.

4. Their severity. In one of my patients, an otherwise healthy man, they had become so frequent and violent that he had discussed with a surgeon the possibility of having the nerves to the intestine severed. Another of my patients (see above) had fainted during the attacks. Mild attacks or abortive ones may however also occur.

5. Their short duration. In most of the cases the pain lasted only a very few minutes. One of the patients said however that it lasted about ten minutes (Case 3). In the same patient the duration of the attacks seems almost constant.

6. The pain is described as gnawing, aching, cramp-like, or stabbing and is often associated with a characteristic tight sensation in the epigastrium or precordium, which makes the patients gasp for breath and gives them the impression of being gravely ill. It is neither preceded by nor followed by tenesmus, nor by flatus or paræsthesia in the rectum or anal region, and it is very seldom of a radiating character.

As a rule the patients had had the pain for several years and could give no conceivable reason for its occurrence, nor was I able to associate it with any definite disease. One of the patients suffered from gastric ulcer, another from colitis with dyspepsia, one from bronchial asthma, and one man was otherwise in perfect health. On some of the patients dilatatio ani violenta had been performed without any relief whatever. One woman was operated on for a retroflexed uterus without result.

I have carefully examined all these patients, except the colleague referred to, including rectoscopy and rectal exploration, but always with an entirely negative result. I have not been able to find any change in the anal region, rectum, or accessible portion of sigmoid flexure which might explain the origin of the pain. I have unfortunately never been able to examine the patients during an attack. But perhaps an examination would be impossible at such a time.

NATURE OF THE CONDITION

The negative result seems to indicate that the pain is of nervous origin. The attacks have nothing in common with the pain associated with anal fissure, hæmorrhoids, coccydynia, or proctitis; they are not associated with tenesmus, nor are they caused by defæcation.

If we assume, and this is the most reasonable explanation, that these attacks of pain have a nervous origin, the question arises whether we can place them among any of the known forms of nervous pain in the rectum—the organ which is clearly the seat of the pain. I have found no mention of it in the Danish, English, French, and American text-books and monographs to which I have access. In 1907 Albu described 5 cases of rectal neuralgia (Mastdarmneuralgie), and stated that the American investigator, S. G. Gant, had given a detailed description of this complaint in his book on diseases of the rectum and anus (published in 1904), a book which I have failed to obtain, but I shall revert later to Gant's description of rectal neuralgia. According to Albu's description—he says that he has been unable to find any mention of it in the German literature—rectal neuralgia is characterised by pain which is intermittent or remittent and located in the rectum from which it radiates to the hip, perineum, and sometimes even down the legs. The duration of the pain varies greatly, from minutes to days, and may recur several times a day.[1] The pain had no relation to defæcation or functional intestinal disorders (constipation or diarrhœa) and occurred in decidedly neurasthenic individuals. Unfortunately Albu does not give the history of his cases, but mentions one where "the rectal neuralgia" was due to cancer of the prostate and was therefore not genuine rectal neuralgia. I will give a brief summary of the history of this case:

A man, 55 years of age, had suffered on and off for several months from violent pain in the rectum and perineum, which at times spread out into the back, but mostly into the right hip and thigh. The pain varied in intensity and could disappear completely, but might be so violent that the patient had no peace by day or night. The pain can therefore be very protracted.

Albu further states that tabetic anal crises can resemble what he understands by rectal neuralgia; I shall return to this point later. Pickardt reported 2 cases of nervous rectal pain, occurring after rectal gonorrhœa, and pointed out the analogy with Albu's rectal neuralgia. It has nothing in common with the attacks of pain we are dealing with, but resembles closely the neurasthenic rectal pain. In A. D. Schmidt's "Klinik der Darmkrankheiten" (1913) neuralgia of the rectum is described as follows: "Wenn wir von den bereits erwähnten Crises anales der Tabiker und der Coccygodynie absehen, kommen neuralgische Schmerzen des Rectums und der Anusgegend nicht allzu selten vor. Sie gehen aus den Hyperæsthesien und Paræsthesien dieser Gegend hervor und kombinieren sich mit ihnen." In his work "Constipation and Allied Intestinal Disorders" the American author S. G. Gant, referred to above, cites some cases of rectal neuralgia in constipated patients, which in no way resemble proctalgia fugax, but correspond far better to Albu's description of rectal neuralgia.

---

[1] The fact that Albu was able to examine his patients during the attacks points to their lasting much longer than those reported here.

There can hardly be any doubt that the rectal pain described by Albu, A. D. Schmidt, Pickardt, and Gant is the same disease. The common characteristic feature of the neuralgia—namely, the intermittent and remittent occurrence of *radiating* pain—is easily recognised from Albu's description. A. D. Schmidt, on the other hand, lays more stress on the paræsthesia and hyperæsthesia so often associated with the neuralgic pain than on the pain itself. The clinical picture briefly described by him corresponds, according to my experience, to the frequently occurring nervous rectal pain. It usually has more the character of paræsthesia and is described as gnawing, burning, or smarting pain which radiates from the rectum to the perineum, genitalia, or sacral region. And although it varies in intensity, its almost constant presence and its resistance to treatment are just the things which make these patients the perpetual despair of many doctors. A patient whom I recently treated for such nervous rectal pain, who was a pronounced neurasthenic, gave it a rather characteristic name—"smouldering pain"—by which he meant that the pain was not particularly severe, but felt like a continuous gnawing in the rectum, spreading out to the genitalia, but of variable intensity.

From the description I have given of proctalgia fugax it is clear that the clinical picture of this disease is quite different from that of rectal neuralgia.

Albu states that rectal neuralgia can be confused with the anal crises in tabes. Lewandowsky gives the following brief description of the latter: "by rectal crises are meant attacks of pain in the rectum associated with a sensation as if a wedge had been shot into the anus." Pierre Marie (Charcot, Bouchard, and Brisseau, Traité de Médecine, 1904) describes the intestinal crises in tabes as being attended by diarrhœa, rectal tenesmus, or hæmorrhage from the anus. Quite apart from the fact that none of the present patients were tabetics or that I have any recollection of any of my other patients being such, proctalgia fugax bears no resemblance to either Lewandowsky's or Pierre Marie's description of anal or intestinal crises in tabes.

But in addition to this nervous rectal pain yet another form of nervous abdominal pain is described under the title "nervous enteralgia or neuralgia of the mesenteric plexus." I have only seen this variety of pain described in German manuals and textbooks (Nothnagel, Strassburger, A. D. Schmidt), never in the Danish, French, English, or American books which have been available to me. Nervous enteralgia, which in earlier days played an important rôle (see Romberg: Lehrbuch der Nervenkrankheiten, 1846), has of later years lost considerable ground. And A. D. Schmidt writes: "selbständige ätiologisch auf andere Weise nicht zu erklärende nervöse Enteralgien habe ich selbst nie beobachtet." I must refer to Strassburger's and Nothnagel's descriptions of the nervous enteralgia which consists of attacks lasting for a longer or shorter period (days), radiates, and is often preceded or followed by slight abdominal pain. The term nervous enteralgia is undoubtedly a scrap-heap, and the attacks of pain described by the above-named authors either include pain in other parts than the intestine—e.g., duodenal or gastric ulcer—or they are the spasmodic pain of spastic constipation, mucomembranous colitis, or lead colic, which are probably due to intestinal spasm. Proctalgia fugax quite lacks the radiating character which these attacks of pain mostly possess, while the abortive attacks are entirely absent before and after the actual severe attack which is of much shorter duration.

It has thus been impossible to find any description which would fit this disease. That it is of nervous origin, is, as already suggested, probable, and it seems most likely that proctalgia fugax is caused by a spasm. This spasm cannot occur in the sphincter ani—even if such a purely functional spasm of this muscle exists at all. Nothnagel maintains that anal spasm is always secondary. The present patients and, as far as I can recollect, all the other patients I have seen, were absolutely sure that the pain was situated above the anal region. The pain in this region is indeed quite familiar to most people and sufficiently characteristic to be identified. If therefore proctalgia fugax is due to spasm, it must be located in the rectum above the anal region or in the lowest part of the sigmoid flexure.

The course of the disease varies very considerably. One patient, an otherwise healthy woman, told me that she had had three attacks in the course of one year; subsequently she felt no trace of pain until many years later when she had a severe attack accompanied by profuse sweating. Other patients suffered for years from attacks which then ceased for a long time, but I have formed the impression that they become less frequent and milder as time goes on.

The *ætiology* of proctalgia fugax is quite unknown; in fact we cannot even determine with certainty whether the pain is primarily nervous or reflected. I think I can say definitely that none of the abovementioned patients were neurasthenics.

It is of course difficult to devise a *treatment* for attacks of pain of such short duration and of such varying frequency as proctalgia fugax. One would naturally regulate the function of the intestine if it was out of order, ut aliquid fiat, and if the pain occurs fairly frequently an attempt might be made to stop it by giving belladonna, luminal, or codeine. Most of the patients I have seen have been content to learn that the attacks of pain were not a sign of any serious illness and did not lead to any.

I propose to call this morbid condition "proctalgia fugax." I am aware that it is a philological heresy to couple a Latin adjective with a Greek substantive, but for one thing it is a very common combination in the names of medical diseases—e.g., erythema fugax—and moreover the term has the advantage that it does not suggest any particular origin of the pain. When asked why I call these attacks of pain proctalgia, I can only answer that it is because the patients themselves refer the pain to the rectum. Moreover, I cannot think of any other organ in the pelvis, common to both sexes, where the pain might be located.

Addendum

Since the publication of my first account of proctalgia fugax in *Hospitalstidende* (1935, No. 3, p. 73) six colleagues have published or informed me privately of their personal experiences. I shall cite some of these cases.

Dr. A. B., aged 42, writes: I have searched in books and asked other physicians about it, but nobody has been able to tell me anything about this perplexing affection with which I have been troubled for the last 6–7 years—fortunately, less often during the past year. Your description of the condition is excellent, but I would like to add a few remarks about my own case. The first attack set in at night after coitus. Since then the pain has again appeared a few times after coitus; but otherwise it sets in without any provocation whatever, most often at night. I have been sound asleep and suddenly I wake up, feeling this excruciating pain in the rectum: at first faintly, then gradually increasing to an agonizing strain which may be so violent that once I fainted from it. I cannot say that the pain is accompanied by a need of defæcation, yet it feels as if I might be relieved if the bowels would move because the rectal strain or pressure is so severe. After the pain has lasted some minutes, it begins to subside and finally disappears, giving way to a state of fatigue coupled with profound gratitude for the end of the agonising minutes. These attacks were never followed by defæcation, nor by urination.

After the first attack it was natural to think of a spasmodic condition of the prostate, but rectal exploration has revealed no abnormality. Nor, as a rule, have I been able to think of any exciting cause of the attack. When it is at its height I feel a longing for a rather hot soapsud enema, but then there is no time to get it ready or do anything. At first I used to go to the w.c. whenever one set in, but as there was no passage of fæces, flatus, or urine, and since I once fell on the floor in a faint, I now lie flat on my back in bed. As regards constitution, I may tell you that I am rather easily upset, and that I have a disposition to migraine and to "neurosis," sometimes cardiac and sometimes gastro-intestinal.

Dr. C. D., aged 47, writes: I have been much interested in reading your paper on proctalgia fugax, a condition my mother and I are painfully acquainted with; I have been troubled with such attacks for about ten years. In both my mother's case and my own the attacks set in most often at night, so that we wake up with pain. Then the pain increases in intensity till it reaches a climax, after which it again subsides. It lasts from 10 to 15 minutes and is always in the same place. The pain is very distressing, so fierce at its height that one is almost crazy with it. I turn pale and sweat profusely. I have tried to examine my rectum during the attack but I have been unable to feel anything wrong. In the last attack the pain began in the left side and passed *in front* of the rectum over to the right side, while *it subsided in the left side*. I have never noticed such a passage of the pain before.

All treatment has been without any effect. I have tried defæcation, hæmorrhoidal ointment containing percaine, digital massage, but all without avail. My mother sits down on the edge of a hard chair and thinks it helps. The attacks have come twice or thrice a year except for one year when they stayed away altogether. I have twice had a sensation of an approaching attack in the daytime but it kept away. For the sake of completeness I may tell you that I have a small fissure of the mucous membrane that bleeds a little now and then, but it never hurts, and it does not appear to be in any way connected with the attacks. Nor are the a ks associated with any disorder of the bowel.

Dr. E. F., aged 70, writes: Proctalgia fugax! Fa whent —now I know a fine name for an affection I h em been acquainted with personally for a good many ye recearly always at night and not with such violent manif esthus as encountered in some of your cases, but disagre om ough whenever it makes its appearance, fortun long intervals. You are right, it has nothing t the anal opening; it seems to be located higher u or sond it feels more like a spasm. If I am to compar on fo with anything else it will be with cramps of the with with which I am troubled with now and then—tho ered it has no connexion with the proctalgia. dysp

I just wonder whether this phenomenon—or was atever one should call it—will not turn out to be rath ne pa ommon now you have drawn attention to it. I have ned w t twice in my practice; I do not remember any de operat of one of these cases, but the other patient was a fo sailor, 50 years old, who described the pain as being eedingly severe. ese p

The information now available on ng rec, whole confirms my description of proctalgia h an ax. But the attacks may evidently last conside e to ly longer than I stated at first, for a colleague of m or a estimates the maximal duration at one hour. T ht ex uggestion that the pain may be relieved by chang unate posture is new to me: one patient is relieved by ring a ng flat on his belly, another on his back, and a third on his side. Moreover, among the latest additional cases, there are two instances in which proctalgia fugax has occurred in the mother or father and in the child.

Another important point is now elucidated more fully. I stated above that the attacks of pain can scarcely be attributable to anal spasm. This view is confirmed by three of the patients who have explored their rectum during the attacks without being able to feel any spasm of the anal region. The only positive finding was that one patient thought he was able to detect some swollen veins in the rectum.

THE TREATMENT OF TETANUS WITH CONTINUOUS AVERTIN ANÆSTHESIA

WITH A REPORT OF A CASE

BY LESLIE COLE, M.D. Camb., F.R.C.P. Lond.
HON. PHYSICIAN TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE

IN tetanus, treatment should be directed along three lines:—

(1) The prevention of any further absorption of toxin by the central nervous system. (2) The control of reflex spasms, which kill by exhaustion or by respiratory spasm and suffocation. (3) The giving of sufficient fluid and food.

Further absorption of toxin which is already present in the wound or in the circulating blood can probably be prevented by giving a large intravenous dose of antitoxin (100,000 to 200,000 international units), and after an interval cleansing or excising the wound. It is not likely that anything can be gained by giving repeated doses of antitoxin. Cole and Spooner[1] have shown that after a single injection of 200,000 units there are still over 10 units per c.cm. in the blood seven days later and 3–5 units per c.cm. fourteen days later. There is no convincing evidence that the injection of antitoxin by the intrathecal or any other route can effect toxin which has reached the cells of the central nervous system. Both theoretical and clinical evidence suggest that the intravenous route is best for neutralising toxin which is still circulating. Lumbar puncture is to be avoided at all costs.

Many drugs have been tried for the control of reflex spasms. Avertin was used in 1928 by Lawen[2] and Lindemann.[3] Momburg and Rotthaus[4] in 1929 gave 63·8 g. during a period of twelve days to a child weighing 20 kg., and were of the opinion that the relief afforded in this case by Avertin during the acute stages of the illness was greater than they had ever witnessed from other sedatives in similar conditions. Since then, many clinicians have given favourable reports of its action.

I have used avertin in 10 cases of tetanus since 1930[1, 5] and have found it better than any other sedative. In severe cases, doses of 0·1 c.cm. per kg. control the reflex spasms completely for periods of from two to six hours and produce relaxation of the jaw and lessening of the tonic rigidity. No ill-effects have followed the above dose given daily for eight consecutive days, and four such doses in 24 hours have given rise to no ill-effects. In no previous case, however, have doses approaching that used in the present case been given.

CASE RECORD

Baby A., aged six and a half days; second child; male. Labour normal. Weight at birth 7 lb. The cord separated on the fifth day after birth. It was dressed with cotton wool before separation and "rag" afterwards. Progress was normal and he took the breast well until six and a half days after birth. It was then noticed that he could not suck and that the jaws seemed to be stiff and the mouth could not be opened. Twelve hours later he was still unable to suck or swallow and he appeared to be stiff in spasms. These symptoms became steadily worse, and he was unable to take any food up to the time of admission to hospital, 36 hours after the onset, when he was 8 days old.

State on admission.—Marked physiological jaundice. Purulent discharge from umbilicus. Trismus and risus sardonicus with complete inability to swallow fluids. Generalised reflex spasms of great severity with opisthotonus occurring every five minutes. These spasms lasted for periods up to two minutes and involved particularly the muscles of the chest, abdomen, and diaphragm so that respiration was completely stopped and cyanosis was extreme. It was clear that if these spasms were allowed to go on they must prove fatal in a few hours at most. They occurred without any apparent stimulus, but were brought on and made worse by manipulation.

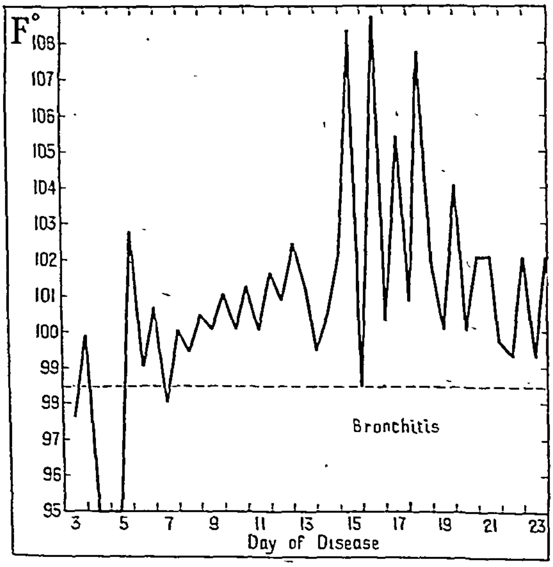

FIG. 1.—Reduced four-hourly temperature chart showing highest and lowest temperature recorded each day (rectal).

Treatment.—The child was anæsthetised with open ether and oxygen. 100,000 units (int.) were given intravenously through the anterior fontanelle and 0·3 c.cm. of avertin was given rectally. Subcutaneous saline, 80 c.cm., was also given. Later the umbilicus was cleaned with hydrogen peroxide, and hydrogen peroxide dressings applied. A stomach tube was passed nasally and left in situ, but some difficulty was experienced in feeding during the first twelve hours.

Progress.—Avertin was found to give complete relaxation and freedom from spasms for periods of from four to eight hours, according to the phase of the illness and the size of the dose. Up to the 9th day larger and more frequent doses of avertin were required, but from then onwards it was found possible to reduce the dose gradually. Immediately the spasms began to recur a further dose of avertin was given, the length of the period of freedom from spasms and the apparent severity with which they started to recur when the effects of the avertin began to wear off, being the criteria on which the next dose was estimated. In this way, for the rest of the illness except on a few occasions, severe spasms were prevented. The few which did occur were due to too long an interval between successive doses of avertin. After the 13th day the spasms were clearly less severe, and avertin was not given so frequently, but only when the spasms appeared to be coming on with particular severity. Avertin was finally stopped on the 25th day of the disease.

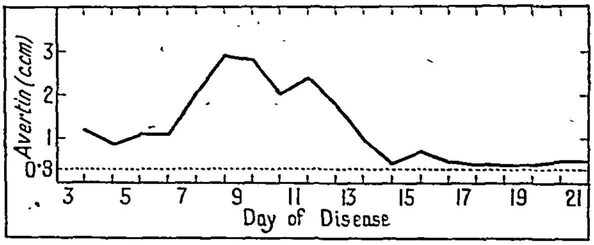

FIG. 2.—Chart showing daily dosage of avertin given.

After the 5th day cyanosis and shallow breathing became more and more marked after each dose of avertin. Warmed nasal oxygen relieved the cyanosis at once. From the 5th to the 20th day it was found necessary to give oxygen in this way for about six hours in every 24, and from the 8th to the 12th day it was given almost continuously. From the 15th to the 20th day there was considerable bronchitis and this probably made the cyanosis worse. Other complications were severe œdema of the scrotum from the 8th to the 12th day, and irritation and prolapse of the rectum on the 12th day, which rapidly cleared up when the dose of avertin was reduced. A slight erythematous rash appeared on the 9th day and gradually faded. This was probably due to the serum which had been given. A pressure sore on the hip was

Theoretical caloric requirement per day 300 calories (given by 15 ounces of milk).		Total avertin	24·4 c.cm.
		Dose of avertin for basal anæsthesia 0·3 c.cm. (0·1 c.cm. per kg.)	

troublesome in the fourth week. Vomiting after feeds in the fourth week was immediately relieved by a stomach wash out.

After the 4th day, little difficulty was experienced with feeding. The feeds were given hourly, and the tube was removed once daily to be cleaned, but was immediately replaced. Extra subcutaneous saline was given on the 17th day, because the weather was intensely hot and the child seemed a little dehydrated.

The temperature chart (Fig. 1) shows the hyperpyrexia which occurred on three successive days and which is characteristic of severe tetanus. Details of the treatment with avertin and feeding are shown in the Table and Fig. 2. The reflex spasms grew gradually less after the avertin had been stopped and ceased on the 35th day. The tonic rigidity then grew gradually less and passed off about the 44th day. The general condition began to improve in the fourth week. On the 25th day the weight was 6 lb. 12 oz., and from then onwards the child gained steadily, being 7lb. 12 oz. on the 46th day, 8 lb. 7 oz. on the 57th day, and 9 lb. 3 oz. at ten weeks. The urine tested on the 30th day was found to be normal. At the age of two months the child appeared to be normal in every way and showed no sign of any mental abnormality or backwardness. The bowels were normal throughout the illness.

DISCUSSION

In the present case avertin produced complete control of the reflex spasms, relaxation of the jaw, and lessening of the tonic rigidity about ten minutes after it had been given. Such relief was maintained for from four to eight hours according to the dose given, and the phase of the disease. The only ill-effect which appeared to be directly due to the avertin was that on the respirations which became increasingly rapid and shallow about ten minutes after it had been given, and cyanosis came on within half an hour. The cyanosis was relieved by nasal oxygen, which had to be given more and more frequently and continuously as the illness progressed. The rectal irritation caused by the repeated doses cleared up quickly directly the doses were reduced in size and frequency. Apart from the above no ill-effects were noted.

It is interesting to note that the curve of dosage, which was determined solely by the period of freedom from spasms after each dose, showed a steady rise to a maximum on the 9th day, and then a steady fall showing that after the first symptoms appear it is many days before toxin produces its full effects, and that these only subside gradually.

The problem of giving sufficient fluid and food in tetanus is a difficult one on account of the combination of trismus and inability to swallow which is present in so many severe cases, and the fact that unless the reflex spasms are under complete control any attempt to feed brings them on. In the present case, the control of the spasms was so satisfactory that a stomach tube could be passed easily by the nasal route. By feeding at hourly intervals it was found possible to give the correct diet for the age and weight on most days. It should be noted that the child was unable to swallow any fluid until the 21st day of the disease. In a previous severe case in an adult, in which swallowing was impossible, I was able to pass a stomach tube under avertin so that the patient could be fed. In this patient the dose of avertin was not repeated for fear of giving an overdose and death took place during respiratory spasm.

How great is the danger of giving large and repeated doses of avertin is not yet known. Parsons [7] has shown that a dose of 0·475 g. per kg. produced fatty degeneration of the liver in a rabbit, so that the danger of toxic effects on the liver must not be overlooked. It is possible too that large and repeated doses given for many days may lead to dangerous cumulative effects. Some patients too may have an idiosyncrasy to the drug. Boyd [10] states that children stand avertin in ordinary doses particularly well. It is possible that very large doses in adults may be more dangerous and less effective. Such considerations emphasise the need for caution in giving large and repeated doses.

I have recently given 0·5 c.cm. per kg. in 27 hours to a five-year-old child with tetanus complicated by lobar pneumonia. Death took place 24 hours later, and histological examination of the heart muscle, liver, and kidney showed that they were normal.

Curare has been tried for the relief of spasms in tetanus,[6] and curarine has been used for the control of the spasms of experimental tetanus in rabbits[8] and has been suggested for human tetanus.[9] The results in this case suggest that avertin used in large doses may do all or more than has been hoped of curare or its derivatives, and that its use may be fraught with less risk.

In considering the result in this case, the exceptional severity of the infection should be remembered. The incubation period could not have been more than six and a half days and was very likely less. The period of onset was not longer than 30 hours, and was probably less. The respiratory spasm was so severe on the second day, that had they not been controlled the child must have died in a few hours at most. Hyperpyrexia occurred on three successive days, the reflex spasms lasted for 35 days, and the tonic rigidity for 44 days. In a series of 22 cases of tetanus which I have treated on the same lines as this case, but without avertin or with comparatively small doses, no case with a period of onset of 48 hours or less has survived longer than five days.

SUMMARY

A case of severe tetanus neonatorum with recovery is described. Treatment consisted of one large initial dose of intravenous antitoxin followed by continuous anæsthesia with avertin for 11 days and smaller doses for a further 12 days. Nasal oxygen was given continuously for long periods and a normal diet by stomach tube which was left in situ. A total of 19·2 c.cm. of avertin was given in the first 11 days, and 24·4 c.cm. altogether in 23 days. The weight of the child was 6–7 pounds.

It is suggested that treatment on the above lines with large and frequent doses of avertin will prove of great value in the treatment of severe cases of tetanus. The need for caution in giving such large doses is emphasised.

INSTITUTE OF MEDICAL PSYCHOLOGY.—Dr. J. A. Hadfield, lecturer in mental hygiene at King's College, London, has been appointed director of studies at this institute (formerly the Tavistock-square Clinic). The increase of educational work carried out by the institute has made it necessary to create this post.

CLINICAL AND LABORATORY NOTES

TETANUS IN A CHILD AGED TWENTY-THREE MONTHS

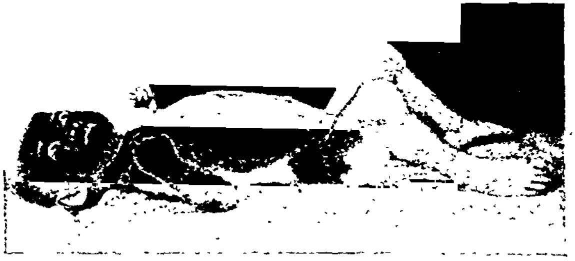
SUCCESSFULLY TREATED WITH ANTITETANIC SERUM

By J. D. Spillane, M.B., B.Sc. Wales
LATE RESIDENT MEDICAL OFFICER, LLANDOUGH HOSPITAL, PENARTH, GLAMORGAN

The following case is reported because tetanus in oung children is now fortunately rare, and because t illustrates the successful use of antitetanic serum n large doses, although the patient had been ill for hree weeks before treatment began. In all, 232,000 units of antitetanic serum were introduced, including 212,000 units intrathecally.

The child, aged 23 months, was admitted to Llandough Hospital on Dec. 21st, 1934. Three weeks previously, when in good health, he had begun to have difficulty in opening his mouth and taking food. Teething was thought to be the cause, but as the condition became more obvious in the next few days the family doctor was called in. He had great difficulty in opening the mouth, the jaws being held tightly clenched. No other abnormal sign was found. During a similar examination next day the patient went into a state of generalised tonic spasm with a prolapse of the rectum. Cyanosis was present and the breath was held, but no clonic spasms occurred. During the following fortnight the patient remained in a state of more or less generalised tonic spasm punctuated at intervals with exacerbations, during which the neck would be thrown back and a condition of opisthotonus produced. During such an attack sweating was profuse and urine voided. The attacks occurred two or three times daily.

On admission the patient was lying on his back with a frightened face and limbs fully flexed (see Figure). Colour and general build were good and consciousness fully retained. Handling was resisted and produced exacerbation of the spasm. The eyes were held practically closed and opening them was difficult. The pupils were normal and no strabismus was detected. The jaws could not be opened and the masseter, temporal, and platysma muscles were in a state of firm contraction. A thin-lipped grin with elevated chin and stiff neck produced a characteristic picture. The sternomastoid muscles stood out, the trunk was arched backwards, and the abdominal muscles board-like and visibly tense. The limbs were held rigidly flexed and could not be extended without using considerable force. The tendon-jerks of arms and legs were exaggerated and an extensor response was elicited on the right side. A marked feature was the retention of perfect consciousness, the patient following every movement with his eyes. No wound could be detected, healing or active, but in view of the rather long course of the disease, this could be readily explained.



Photograph of the patient, showing the mental alertness, the rigidly flexed limbs, and the slight opisthotonus

A diagnosis of tetanus was made, meningitis being excluded because of the mental alertness and the marked trismus. Lumbar puncture revealed a clear fluid under pressure: it contained no excess of cells and gave a negative *Nonne-Apelt reaction*; chlorides and sugar were normal.

Treatment.—On the day of admission (Dec. 21st) 40,000 units of antitetanic serum (A.T.S.) were introduced by cisternal puncture and 20,000 units intramuscularly. On the 22nd the condition was unchanged; breathing laboured and sweating marked. 40 c.cm. of cerebrospinal fluid (C.S.F.) removed by cisternal puncture and 40,000 units of A.T.S. introduced. Dec. 23rd: slight general improvement. 20 c.cm. of C.S.F. removed by cisternal puncture and 20,000 units of A.T.S. introduced. Dec. 24th: condition unchanged. 10 c.cm. of C.S.F. removed by lumbar puncture and 12,000 units of A.T.S. introduced. Dec. 25th and 26th: 10 c.cm. of C.S.F. removed by cisternal puncture and 40,000 units of A.T.S. introduced each day. By the 26th there was little improvement in the general rigidity, but exacerbations were becoming infrequent. Dec. 28th: 5 c.cm. of C.S.F. removed by cisternal puncture and 20,000 units of A.T.S. introduced. Jan. 2nd, 1935: general improvement. Trismus less, so that the infant opened its mouth sufficiently to allow the insertion of the little finger. Facial spasm less evident. Jan. 4th still some head retraction and arching of the back Limbs held flexed but less rigid.

During the following week improvement was rapid and the infant put on weight and improved in colour. By Jan. 15th he was apparently normal, the knee- and ankle-jerks were very brisk, however. One noticeable feature during convalescence was the high degree of intelligence he betrayed and the alertness with which he appreciated his surroundings.

The fact that this child had already survived three weeks' illness before admission to hospital meant that the prognosis was favourable before the commencement of serum treatment. It was noticeable, however, that the child's condition began to improve soon after serum was given; whereas he had been getting worse until he came to hospital.

My thanks are due to Dr. A. G. Watkins and Dr. D. G. Morgan for permission and help in publishing the notes of this case.

STONES IN THE HEPATIC DUCT

A REPORT OF TWO CASES

By Leonard Ley, M.B., B.Chir. Camb.
SURGEON TO THE GREAT YARMOUTH GENERAL HOSPITAL

The method of treatment suggested in this note, and adopted in Case 2, is based on what happened in Case 1.

Case 1.—Mr. A., aged 46, was under my care in 1924 for gall-stone colic and jaundice. He underwent operation on Aug. 7th, 1924, when the jaundice had cleared up. At operation I found the gall-bladder shrunken and attenuated and containing only a few tiny stones. I opened the bile duct and explored with my finger, but found no stones. The gall-bladder was removed and the bile duct drained; a large cigarette drain was also introduced.

Shortly after the operation I went for my holiday. On my return I was told the following story. My patient became very ill with pain, jaundice, and high temperature; and after several days the sister, who was dressing him, noticed some dressing protruding. This was removed and was followed by a copious gush of bile and a very large number of small stones.

The patient's general condition rapidly improved and he has remained perfectly well ever since. I assume that in withdrawing the drainage tube the gauze within remained adherent to the bile duct and that this blocked the duct and caused a damming-back of bile with dilatation of the ducts; when the pressure was released the flood washed out the stones.

This was a case where a surgical blunder cured what orthodox treatment would almost certainly have failed to relieve.

CASE 2.—Mrs. B., a stout woman aged 59, was admitted under my care on May 11th, 1933. Sent in by Dr. J. M. Smellie as a case of gall-stone colic. History of indigestion for two to three years, varying with attacks of severe pain. Last attack five months ago. Never had jaundice. At operation on May 22nd, the gall-bladder was found enlarged and thickened and contained stones. The common bile duct was much dilated and felt "mushy" with stones. The gall-bladder was removed and I then opened the bile duct and removed all the stones it contained with the finger in the duct aided by a scoop. When the main duct was emptied I could feel a stone presenting at the orifice of an accessory duct that I took to be the left hepatic duct. This was coaxed out by an angled probe and was promptly followed by another. In this way I removed six or seven stones and could feel no more, but naturally felt that it was more than likely that other stones were present. I decided to pack the common bile duct with ribbon gauze and so dam back the bile and trust the released flood of bile to wash out any stones left behind.

I first put a Spencer Wells forceps on each lip of the incision in the bile duct to act as scaffolding, I then tightly packed the upper end of the bile duct with ribbon gauze, and put a large corrugated rubber cigarette drain down to the bile duct. The wound was closed above and below the drain, leaving about 2 inches of the abdominal wall unsutured. The ribbon gauze and drain and the Spencer Wells were removed on the third day under gas anæsthesia and the duct was explored digitally—five stones were removed. I dressed the wound daily and explored it digitally for ten days, removing three more stones. No anæsthetic was required after the first dressing. She had only one hypodermic of morphia, gr. ¼, after the operation. She left hospital with the wound soundly healed on July 29th, 1933.

This second patient is now (in June 1935) perfectly well and has had no symptoms of any abdominal disease since her operation.

MEDICAL SOCIETIES

ASSOCIATION OF CLINICAL PATHOLOGISTS

THE summer meeting of this association was held in the pathological department of the Princess Alice Memorial Hospital, Eastbourne, on July 20th. Dr. A. G. SHERA, pathologist to the hospital, being in the chair. Dr. R. A. O'BRIEN (London) spoke on certain problems in connection with

Diphtheria Prophylactics

It was admitted, he said, that by the use of prophylactics it was possible greatly to reduce the incidence of diphtheria in a community; in Birmingham fever hospitals the introduction of prophylactic immunisation had reduced the incidence from 10 per cent. to almost nil. The problem now was to determine the most suitable prophylactic, and to ensure its intelligent use. There is, he said, no absolute line of demarcation between Schick-positive and Schick-negative individuals. Subjects whose blood showed 1/30th of a unit of antitoxin would give a negative Schick reaction; those possessing less than 1/1000th of a unit would give a positive reaction. The response to any given prophylactic depended to a large extent upon the existence of some potential antibody; those showing some degree of this basal immunity gave the best response to prophylactic immunisation. The response to any given prophylactic varied enormously in relation to this basal immunity; it was on the whole more difficult to produce a satisfactory response in children from sheltered homes than in those who had mixed widely with other children of all ages. On this account it was difficult to dogmatise as to the most effective method of diphtheria prophylaxis and result. Much still remained to be learnt as to the chemical constitution of alum toxoid. Different samples gave a nitrogen content of from 0·2 to 3·0 mg. per c.cm. The American requirement was that alum toxoid when injected into a guinea-pig in a dose of 1·0 c.cm. should produce two units of antitoxin in six weeks. He had tested a number of alum toxoids both American and English; few of these had reached the American requirement, but one sample made in London had, in certain guinea-pigs, produced five units. Mr. Glenny found that guinea-pigs gave a better response to two doses of 0·1 c.cm. at an interval of some days than to one of 1·0 c.cm. Answering questions put to him by practitioners, Dr. O'Brien said that the Schick-negative child cannot be regarded as absolutely safe against diphtheritic infection; a heavy dosage of a virulent organism may overcome the immunity, but the infection would almost invariably be clinically mild. The Moloney-negative reactor is virtually though not absolutely safe against unpleasant manifestations after immunisation; immunisation does not for practical purposes "sensitise" the subject. Dr. O'Brien pointed out that no matter what form of prophylactic has been used, the treated subject cannot be regarded as immune unless the immunity is demonstrated by a Schick test.

Prof. J. W. MCLEOD (Leeds) stated that in Leeds 19 cases of mild diphtheria had developed among over 30,000 children treated with diphtheria prophylactic. Nine of those children were known to be Schick-negative; the remaining 10 had not been tested.

BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA.—Prof. MCLEOD spoke of the difficulties and a contribution made by new methods to their solution. He showed cultures of the gravis, intermediate and mitis strains of *C. diphtheriæ* growing on tellurite medium and demonstrated the differences in these strains, both cultural and morphological. On this medium 11 per cent. of positive throat swabs had shown *C. diphtheriæ* against 3 per cent. on ordinary Loeffler medium. There was a wide difference in virulence between the three strains. Of the gravis strains all were pathogenic to the guinea-pig, of the intermediate strains about 94 per cent. and of the mitis strains 86 per cent.

Whooping-cough

Dr. A. D. GARDNER (Oxford) said that although in domestic circles whooping-cough is still taken comparatively lightly, its mortality equals that of scarlet fever and diphtheria combined. For the prevention of epidemic spread it was essential for diagnosis to be made before the whoop developed. In this catarrhal stage bacteriological diagnosis alone was possible. After the second week the characteristic lymphocytosis developed and the complement-fixation test became positive, but it was then too late to prevent spread. Dr. Gardner described his method of isolation of the Bordet-Gengou organism by getting the patient to cough upon specially prepared serum plates. The proportion of positive cultures obtained in the first week was very high; after this it fell away; a positive culture was rare in the fourth week and it was doubtful if the subject remained infective to this stage. He was of the opinion that infection was always from case to case and that carriers do not occur. He was sceptical of the value of pertussis vaccine in treatment. In prophylaxis it was of value, but the organism used to prepare the vaccine must be freshly isolated and of a smooth strain; old rough cultures were of little use. Failure to produce satisfactory immunity in the past had been due to the use of old rough strains. Dosage must be large. He showed graphs illustrating the good results obtained by workers, particularly in the Scandinavian countries, by the use of large doses of a suitable vaccine in the prevention of epidemics.

In the discussion it was pointed out that pathologists working in small laboratories find it impossible to keep on hand a stock of the special medium necessary for the isolation of *B. pertussis*. In Denmark plates of suitable medium in metal Petri dishes are made available by the State Laboratory. Dr. Gardner hoped something of the sort could be done in this country.

Glandular Fever

Dr. L. E. H. Whitby (London) spoke of the infectivity of glandular fever. One patient had infected two attendants; in both cases the incubation period was one week. He had escaped infection himself, but he had, he thought, already suffered from the disorder, though it had been diagnosed as scarlet fever. After the incubation period there was fever lasting for about a week which might give rise to suspicion of enteric infection; glandular enlargement appeared in the second week and might be accompanied by considerable enlargement of the liver and spleen. The swelling affected the glands very irregularly; in some cases only the mediastinal or abdominal glands might be involved, when abdominal pain might suggest operation. The characteristic blood changes appeared in the pyrexial stage; the typical blood picture showed white cells 20–40,000 with 70 to 80 per cent. of mononuclears; these might be small lymphocytes or resemble monocytes. He demonstrated the Paul-Bunnell reaction which depends upon the fact that sufferers from this order develop within their serum heterophile antibodies against sheep red cells. The reaction becomes positive with the appearance of the glandular enlargement; how long it remains positive is not yet known. A titre of 1 in 100 may be regarded as diagnostic.

Dr. Weston Hurst (London) dealt with the clinical pathology of the virus diseases. The virus, he said, localises itself within the cell and therefore tissue reactions are not found. Such focal lesions as occurred were necrotic and marked by an absence of the cells usually associated with infective processes. For the demonstration of inclusion bodies he recommended routine fixation in Zenker's solution with acetic acid.

Dr. Shera described the mode of preparation of sensitised hæmolytic streptococcal vaccine and showed charts and case records from cases of hæmolytic streptococcal infection in which it had been used.

Dr. S. C. Dyke (Wolverhampton) described a case of aspirin poisoning.

REVIEWS AND NOTICES OF BOOKS

The Story of the Middlesex Hospital Medical School

By H. Campbell Thomson, M.D., F.R.C.P. London: John Murray. 1935. With 52 Illustrations. Pp. 182. 10*s.* 6*d.*

Rarely is an institution blest with so charming a writer to chronicle its story as is the Medical School of the Middlesex Hospital in the person of Dr. Campbell Thomson. Here is a living picture of the past depicted with the skill of an artist steeped in the traditions of his alma mater. "Where'er we tread 'tis haunted, holy ground"—no matter whether we are conducted over the Marylebone Fields in 1757, with perhaps a visit to the "Queen's Head and Artichokes," whether we listen with Charles Bell, newly arrived from Edinburgh, to the watchman calling "One o'clock and a starlight morning," or whether we "walk the hospital" with Charles Murchison in the 'sixties. All is unfolded with inimitable grace and sympathy. It will thrill the heart of every Middlesex man to move about in company with the men who founded his school, who fostered it with undaunted courage through many anxious years, and who, with ungrudging endeavour, have steered it to the honoured position it holds to-day. To a wider public it will make its appeal as an entrancing picture of medical life in London in the last hundred years. By a happy circumstance the centenary celebrations of the school have coincided with the completion of the rebuilding of the hospital, so the curtain falls on a great achievement.

Chapters are devoted to various epochs in the school's history, and each contains the names and deeds of those who played their part. One deals with the developments which finally led to the amalgamation of the school with the hospital, another with the War years, and yet another with contemporary events. At the time when various medical schools under the ægis of the University of London were establishing full time professorships in clinical subjects the Middlesex Hospital Medical School chose a different course. A number of appointments were created by which the pathological laboratories—and the school was fortunate in possessing a pathological institute through the generosity of Sir John Bland-Sutton—might be kept in close touch with the clinical side of the hospital. These were in the main full time appointments and included one or two junior members of the honorary staff, who were thus given an incentive to carry out scientific work at their own hospital instead of seeking other hospital appointments and paid posts elsewhere. This course of action, combined as it was with the endowment of professorships in non-clinical subjects, has proved of the greatest advantage to the school, not only in the reorganisation of teaching but in other respects.

We learn that the vexed question of the admission of women students first came under consideration in 1861. Miss Garrett (afterwards Mrs. Garrett Anderson) had taken the unprecedented step of endeavouring to obtain a medical qualification in Great Britain. She obtained permission to attend classes of the preliminary sciences in the medical school. Later, when she was allowed to visit the wards in company with the resident officers, the innovation created so strong a feeling among the students that a petition of protest was sent to the school committee. The lecturers, though apparently individually inclined to support Miss Garrett, collectively failed to face the storm, and a resolution was carried to the effect that "This meeting considers it very inexpedient that female students should follow the practice of the hospital and that the medical officers be earnestly requested not to permit any such persons to attend in the wards or out-patient room." An offer from Miss Garrett to endow a medical scholarship for women students at the Middlesex Hospital was declined.

The book is beautifully printed in large type and contains many excellent illustrations.

A Text-book on the Nursing and Diseases of Sick Children

For Nurses. Second edition. By Various Authors. Edited by ALAN MONCRIEFF, M.D., F.R.C.P. Lond., Physician to the Children's Department, Middlesex Hospital; Physician to Out-patients, the Hospital for Sick Children, Great Ormond-street. London: H. K. Lewis and Co., Ltd. 1935. Pp. 583. 15*s*.

NOTWITHSTANDING the limitation implied in the title of this book, we would bring it to the attention of medical students. The first part is devoted to a consideration of the general principles of medical and surgical nursing, with special reference to the technique and apparatus of the procedures described; separate chapters are devoted to anæsthesia, orthopædic surgery, fractures, shock, and so forth, and brief descriptions are given of a number of the commoner tumours, cysts, and deformities. The second part, which forms the major portion of the whole volume, constitutes an elementary text-book of children's diseases. It is not quite clear on what principle some surgical conditions have been included in the first part and some in the second, but apart from this minor peculiarity of arrangement, the book is well adapted for rapid reference. It is profusely illustrated with many excellent line drawings and photographs, and the general production maintains a high standard. A few inaccuracies that occurred in the first edition have now been corrected. The editor is to be congratulated on his success in welding the contributions of a number of authors into such a well-designed whole.

Diet Control

By GEORGE E. ANDERSON, M.D., Attending Physician to the Brooklyn Hospital and the Lutheran Hospital; and P. C. ESCHWEILER, M.D., Assistant Attending Physician to the Brooklyn Hospital and the Methodist Episcopal Hospital. New York: Gallo and Ackerman, Inc. 1935. Pp. 41, and many diet prescription forms. $3½.

THIS book is an interesting novelty consisting of a large number of diet prescription forms in a loose leaf binder arranged in such a manner that the practitioner can employ them for individual patients requiring diets for the treatment of such conditions as diabetes and obesity. Further supplies of the prescription forms can be obtained from the publishers when the originals are exhausted. An introductory brochure of 41 pages describes the principles to be applied in using the prescriptions. The system is that in use in the metabolic clinic at the Brooklyn Hospital, and contains well-arranged tables for the estimation of the calorie content of diets containing varying amounts of carbohydrate, protein, and fat.

The work is clearly one of those of interest to English readers merely as an indication of a method, because in actual practice the ingredients of the American menu differ fundamentally from our own; the British practitioner is unlikely to order kohl-rabi, rutabagas, or zuzu crackers in any quantity for his patients.

An Introduction to Gynæcology

Second edition. By C. JEFF MILLER, M.D., Professor of Gynæcology, Tulane University School of Medicine; Chief of the Department of Gynæcology of Touro Infirmary; Senior Visiting Surgeon, Charity Hospital, New Orleans. London: Henry Kimpton. 1934. Pp. 354. 25*s*.

DIRECTING attention to the dimensions of the scholarly and comprehensive treatises on gynæcology, which he provided for students and practitioners in America, Dr. Jeff Miller expresses his belief that they do not meet the need of the "beginning student." He offers this as an excuse for the publication of an Introduction to Gynæcology, and modestly states that in a book of this size the subject of necessity could only be presented in the barest outline. In this country such an explanation would prepare us for yet another of the pocket monographs; but, on the contrary, Dr. Miller does indeed introduce the subject in an admirable way. Pathology predominates, as it should, and a very nice balance has been maintained in the relative allocation of space to symptomatology, examination, and treatment. The paper, printing, and production are of the best; the same cannot be said of the illustrations, many of which, especially the photographs, have reproduced badly. The short bibliography appended to each chapter will be of value to students, and could be inserted with advantage in a greater number of text-books published in this country. If the "beginning student" masters this Introduction, he will assuredly have a sound foundation on which to build from his clinical experience.

British Journal of Surgery

THE July issue (vol. xxiii., No. 89) includes the following papers: Carcinoma of the Gall-Bladder, by C. F. W. Illingworth (Edinburgh). A clinical and pathological study based on knowledge of 50 cases. (See annotation on p. 261.)—The Operative Treatment of Fibrous Stricture of the Rectum: with the Description of a new Technique, by J. P. Lockhart-Mummery and O. V. Lloyd-Davies (London). The treatment of low annular stricture by internal proctotomy and repeated dilatation is briefly described. The new treatment for tunnel strictures consists of (*a*) clearing up the local sepsis; (*b*) in most cases, performance of preliminary colostomy; (*c*) operative approach to the rectum by excision of the coccyx; *longitudinal division of the stricture*; and closure of the incision transversely by two layers of sutures.—Notochordal Tumour of the Cauda Equina in a child of Eight Years, by V. H. Ellis (London). The tumour was pedunculated, entirely intrathecal, and histologically had the structure of a chordoma. Operative removal was successful.—Carcinoid Tumour of Meckel's Diverticulum: Report of a Case, by I. Price (London). The patient, a woman aged 54, developed acute peritonitis. She died after a resection of 13 cm. of small intestine, including the growth. The histology is discussed and literature briefly reviewed.—Incisional Hernia, by E. S. J. King (Melbourne). Escape of abdominal contents between peritoneal sutures, or through tears or hiatus along the line of peritoneal closure—and not stretching of the scar—is regarded as the underlying cause of incisional hernia.—Posterior Segmental Block-Excision of the Bladder Neck with Primary Closure, by S. Harry Harris (Sydney). An operation designed for the relief of obstruction such as may be caused by median bar formation, or disease of the posterior commissure, or general prostatic fibrosis; it consists of wedge excision of posterior lip of the urethra by the transvesical route.—A Case of Hyperinsulinism relieved by Partial Pancreatectomy, by J. Allan Berry (Napier, New Zealand). A clinical description is given of functional hypoglycæmia. The blood-sugar curves before and after removal of 28 g. pancreas are described and illustrated. The curious response to starvation and to glucose administration is discussed.—Congenital Dermoid Cysts and Sinuses of the Limbs, by M. J. Bennett-Jones (Liverpool). The anatomical localisation of these sinuses and cysts along the axial lines of the limbs is well illustrated by the five cases reported.—Acromegaly, by R. Lawford Knaggs (Newton Abbot). A historical survey is followed by a detailed description of the clinical features, and of the pathological nature of the skeletal changes. The pathogenesis, and the possibilities of treatment by irradiation, surgery, and glandular therapy are discussed.—Pseudo-Myelomatous Carcinomatosis, by L. Cosin (London). Full details are given of a case, with the typical features of splenomegaly, anæmia, with nucleated red cells and myelocytes, and the X ray picture of multiple myelomatosis. The primary lesion was bronchial.—Omental Torsion with Unusual Symptoms, by C. R. Salsbury (Kingston, Ontario). A description of two cases.—Strangulated Internal Hernia: Report of Cases of Strangulation in the Fossa Iliaco-Subfascialis and through the Foramen of Winslow, by G. F. Langley (Bristol). The second case was one of double obstruction—i.e., of the jejunum in the lesser sac, and of the pelvic colon by inflammatory fibrosis. The literature is reviewed.—The Value of the Urea-Clearance Test in Urinary Surgery, by E. W. Riches and J. Douglas Robertson (London). The technique of the test is described, and its reliability assessed in prostatic surgery, and in surgical diseases of the kidneys.—The Effect of Tracheal Occlusion on the Hypertrophy of Thyroid Transplants and Remnants, by E. Walter Workman and Gavin Miller (Montreal). Experiments were done on adult male and non-pregnant female guinea-pigs, stenosis being produced by partial ligature of the trachea. Hypertrophy followed partial extirpation of the gland. Partial tracheostenosis induced colloid states of the thyroid.—Cholecystography: its present Clinical Value, by Robert McWhirter (London). Includes an analysis of 4676 cholecystographic examinations at the Mayo Institute.—An Unusual Tumour of the Neck, by R. E. Norish (London). Histologically the tumour showed epithelium of an alveolar structure, lying in a mass of lymphoid tissue. The possibilities of origin from branchial tissue or from salivary remains are discussed.—Pathological Changes induced in the Mamma by Œstrogenic Compounds, by Harold Burrows (London). Hunterian lecture. The author regards the effect of œstrin as increasing the liability to cancer of the breast, rather than as directly causing it. Of 125 mice treated, 2 have developed cancer.—The Innervation and Muscular Activities of the Distal Colon: With a Note on the Surgical Treatment of Constipation, by Hugh C. Trumble (Melbourne). The indications are discussed for division of the lumbar sympathetic supply to the colon; of the lumbar sympathetic trunks; and of the hypogastric nerves.

NEW INVENTIONS

AN IMPROVED PNEUMOTHORAX NEEDLE

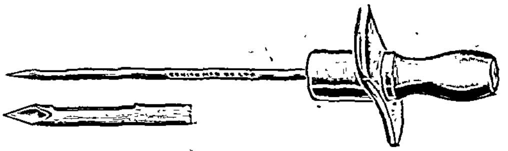
THE needle shown in the accompanying illustration was first manufactured to my specification by the Genito-Urinary Mfg. Co., some two and a half years ago. The needle combines the following advantages:—

(1) The solid end enables so sharp a point to be obtained that many patients find a local anæsthetic quite superfluous.

(2) The side opening in the form of a slit offers less resistance to penetration of the skin and allows the shaft of the needle to be of finer bore than in those models in which a circular opening is used. No stilette need be used, as blocking of the opening with blood or tissue from the chest wall (so common with end-opening needles), practically never occurs.

(3) The butt end of the needle fits directly on to a rubber tube, no tap being required. It will also fit a record syringe so that a sample of fluid can be withdrawn if desired.

This needle cannot be used for the induction of a pneumothorax or for the first two or three refills, since the side opening makes it necessary to push the needle one-eighth of an inch deeper into the pleural space than is the case with an end-opening needle. The risk of injury to the lung is diminished by the absence of blocking of the needle which is the commonest cause of too deep penetration.



I have had similar needles of wider bore made for *aspiration of fluid*. The side opening again has the advantage of not blocking nearly so frequently. The solid, sharp point permits forceless penetration of the chest wall even with a wide-bore needle.

No originality is claimed for any particular feature of this needle, which is only a slight modification of one previously designed (with circular side-opening) by Dr. F. G. Chandler. Acknowledgment is also due to Mr. R. Schranz of the G.U. Mfg. Co., to whose technical skill this needle owes most of its popularity.

ANDREW MORLAND, M.D., M.R.C.P. Lond.
London, W.

1. STOMACH-HOLDING FORCEPS

THE accompanying illustrations show the principles and action of forceps which I have designed and employed in suitable cases.

The first (*Fig. 1*) is a forceps primarily designed for seizing and holding the stomach in such operations as gastrectomy and gastro-enterostomy. It has been developed from the forceps that Pierre Duval designed for holding the lung, and the principal features of the instrument are: (1) while the blades are still triangular they are not fenestrated and the corners have been carefully rounded off; (2) the grip is obtained by means of a small raised piece of metal in which transverse longitudinal grooves are cut; (3) the blades are very light and springy and lightness and accuracy of pressure have been ensured by—(4) the long ratchet.

The second instrument (Fig. 2) is also designed for holding the stomach and intestines, and the figure gives an excellent idea of the tool. They are light and bowed and there is again the long ratchet;

ribbed rubber is threaded round the ringed gripping extremity. This instrument is excellent for holding the small intestine, but may be rather severe at times on the stomach. It is useful for holding the free edge of the liver—for example in local resection of that organ; and it can be used for holding a kidney or gall-bladder, but not all kidneys or gall-bladders are suitable for this type of grip.

FIG. 1

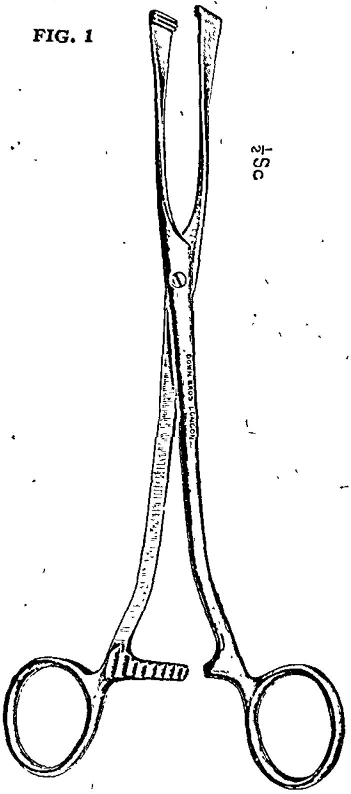


FIG. 2

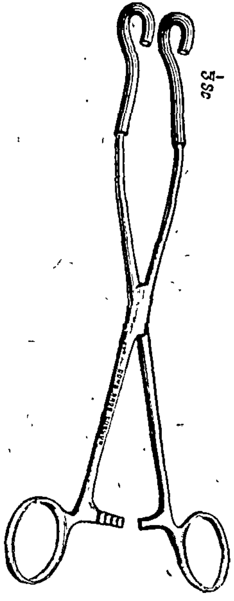

2. A DRAIN INTRODUCER

This instrument is intended to facilitate the introduction of drains into the peritoneal cavity, and the illustrations (Figs. 3, 4, 5, and 6) give a good idea of the method of using it. I employ it largely in conditions such as perforation of duodenal or gastric ulcers where I am in the habit of making a mid-line supra-umbilical incision. The "introducer" is slipped into the lower angle of the wound and kept in intimate contact with the peritoneum along the middle line down to the level at which it is proposed to place the drain. The handle is then slightly depressed while the instrument, as a whole, is slightly raised. With the aid of this manœuvre the cup-shaped end of the instrument causes small areas of the suprapubic part of the abdominal wall to project. In fat individuals projection may not be visible, but can be readily felt. A small incision is made over the projection and with the point of the knife is deepened through all the layers of the abdominal wall right into the cup. Still holding the instrument firmly and steadily a curved artery forceps, about seven or eight inches in length, is pushed into the opening thus made into the cup. As the instrument is withdrawn the artery forceps is simultaneously pushed further in—its point remaining in the cup all the time. In this way the artery forceps ultimately reaches the lower angle of the wound. Its blades are opened sufficiently to seize a piece of split rubber drain about half an inch or thereabouts in diameter. The opening of the blades naturally widens the peritoneal and aponeurotic part of the incision. By withdrawing the artery forceps one end of the drainage tube is pulled through the small stab-hole, the other end is then placed to best advantage in the bottom of the pelvic cavity.

THE LANCET

LONDON: SATURDAY, AUGUST 3, 1935

CONTRACT PRACTICE

HE extension of contract practice provided asion for an interesting debate during the ıual representative meeting of the British lical Association this year.[1] Three different isions had put forward motions asking for the ration of a resolution of the Representative dy dating back to 1920 so as to permit the ncil of the Association to sanction schemes for provision of medical attendance on a contract sis to persons whose incomes are above the tional Health Insurance Acts limit of £250 per num. One speaker recalled that the resolution question was originally passed in 1913, and he umerated some of the arguments which were ought forward at that time. It was said then t contract practice was not good for either tient or doctor, that it was derogatory to the ofession, and that any extension of such practice uld pave the way for the inclusion of the pendants of insured persons under the provisions the Insurance Acts. How remarkable has been change of opinion during the intervening cades is demonstrated by the fact that an endment to the three motions, expressing their mmon intention, was passed by a majority of 8 to 37, and the minority figure actually exag- rates the opposition to the extension of contract actice, since a number of the contrary votes were st against the principle of local option.

How are we to account for this changed attitude ? hat are the arguments which have induced most edical men to withdraw their opposition to ntract practice, and some of them, notably nong the younger ones, actually to press for its tension ? Probably the most effective argument s been the comparatively successful working of e Insurance Acts. There are nevertheless still any who, while participating in work under the cts, look on their compliance as "making the st of a bad job" and who feel—and sometimes y—that the profession in undertaking and couraging such practice is losing dignity and restige. If this were true it would undoubtedly rovide a strong case against contract practice ; ut nearly all the available evidence is to the ontrary. There is nowadays no significant oppo- ition among the insured population against the rovision for medical benefit, and the various ssociations of insurance committees have for a umber of years been pressing for the extension of edical benefit to dependants. The sons and laughters of comparatively well-to-do parents, hen they are in insurable employment, are ncreasingly prepared to accept medical benefit, and many movements are on foot among middle-class people to make provision by insurance on a contract basis for medical attention. No unbiased observer can fail to conclude that there is in our own as well as in other countries a growing belief in and demand for insurance provision of this kind. It is a usual assumption of those who see all good to lie in the past that the peoples of this island are a thriftless spoon-fed lot compared to their forefathers; but the mounting turnover of nearly all the insurance companies constantly disproves such assertions, for what is insurance but a modern and intelligent form of "putting something by for a rainy day" ? There is indeed ample evidence that the general public is gaining faith in contract practice and believes it to be good for the patient.

It remains to be considered whether it is also good for the doctor, and, most important of all, whether or not it is the system most likely to promote national health and well-being. The first need is to differentiate clearly between modern contract practice and the old-time club practice. Those who remember the evils of the latter and the stubborn and successful fight in our columns for its abolition may well dread any risk of a return to this pernicious system, and one can sympathise with their fears. The profession in this country has always condemned any system in which the doctor's position depends on political or any other than strictly medical considerations, and it is not likely to depart from this attitude. But there is a vast difference between being elected as a club doctor and being selected from a panel by an insured patient as his medical adviser, and we have no fear that any extension of contract practice on modern lines will diminish the prestige and independence of the family doctor. The most frequently urged objection to the contract system from the doctor's point of view is that it involves him in a lot of unnecessary and trivial work. It is probably true that the insured worker often comes to his doctor with complaints for which in the pre-insurance days he would have attempted to treat himself in order to avoid incurring a bill. As an offset to this, however, we have to reckon the probable effect of early consultation in serious illness in lessening the total amount of work that the doctor has to do for his practice. Theoretically at any rate the system puts a premium on health and not on illness, and the better the doctor does his job the less he has to do for his remuneration. In prolonged illness under a fee system, unless the patient is comfortably off, the conscientious doctor is placed in the awkward dilemma either of reducing his fees to the charity level at the risk of offending the dignity of his patient, or of reducing his visits at the risk of neglecting his job. This difficulty does not arise in contract practice. Financially the system, while precluding the amassing of large sums, has the advantages of security of income. At the average level of medical income in this country most people would consider that the advantages of security outweigh its disadvantages. It is no argument against the contract system to say, as is sometimes said, that its remuneration is inadequate. The remuneration obviously depends on the capitation rate which may be set at any figure agreed on after negotiation, and adequacy and fairness are at least as readily attainable in this as in any other system, since it operates on the law of averages.

---

[1] See THE LANCET, July 27th, 1935, p. 208.

Finally we have to consider whether this system will aid in the achievement of a better standard of health among the people. Medicine, like industry, is suffering from the prevailing economic disability. There is not much wrong with the production of medical knowledge, but the distribution of it among the people of the country is far from satisfactory. It is probably not an exaggeration to say that if our present-day knowledge of nutrition, hygiene and preventive medicine generally were made readily available for all and effectively put into practice the resultant saving in sickness benefit alone would more than cover the outlay involved. The whole conception of the medical problem rests nowadays on a wider basis, and illness is coming to be regarded not so much as a morbid process but as a biological failure. It is being increasingly realised that prevention of that failure is at once simpler, less expensive and more effective in its results than the attempt to rectify it when it has occurred. The function of the medical man should in the future tend more and more to be that of the expert human biologist, giving advice to those in his care on how to achieve and maintain the fullest measure of health and vigour. Two things are clearly necessary if a development of this kind is to occur. First the doctor must be in the relation of trusted family adviser to his patient, and secondly he must be readily available and in a position to offer his advice whenever he thinks it necessary and not only when called in to attend a sick patient. It may well be that the ultimate solution of the proper adjustment of his relation will be found to lie in the more general adoption of the contract system. At any rate local option as to its development can hardly do harm.

THE TREATMENT OF TETANUS

IN general practice tetanus is a rarity, but it is one of those rarities which lies on the conscience of the general practitioner, for it is amenable, at least in some degree, to treatment, and to that end diagnosis must be prompt and proper management must be instituted immediately. If the chance of meeting with the disease in this country is small it is nevertheless widespread, since tetanus spores are abundant in the soil of the inhabited areas, and quite common in the fæces of farm animals. No doubt they often gain entry to wounds and abrasions, but fortunately they do not produce the tetanus toxin unless they are allowed to germinate and then grow for a day or two; and being anærobes, they can do this only in the absence of oxygen—that is, only when the wound is deep or is scabbed over, and when other organisms or foreign bodies have so damaged the tissues as to hinder their permeation by oxygen from the capillaries. Hence tetanus is rare, but since the conditions favouring it are always likely to occur from time to time, in small wounds as in large, the disease is not likely to disappear. The toxin once produced spreads freely, undamaged by oxygen, and is taken up by the lymph and into the blood. Thence it enters the nervous system through the peripheral endings of the motor nerves all over the body. It travels up their axons into the central nervous system and there produces the spasms and convulsions of the disease by poisoning the anterior horn cells and the corresponding cells in the brain stem; "lockjaw" is early, and therefore ominous, because the journey up the fifth nerve is short, and the first stiffening, in the jaw muscles, is quickly noticed by the patient.

Specific treatment with antitoxic serum has been as disappointing in tetanus as it is successful in diphtheria. The reason is that the antitoxin can neutralise the toxin only in the blood stream; it cannot follow the toxin into the nervous system through the multiple wicket-gates of the motor end-plates, and it cannot reach the nerve cells themselves by any other route. Even FILDES and FLOREY's ingenious attempt[1] to suck it in osmotically from the cerebro-spinal fluid, by giving serum intrathecally and hypertonic saline intravenously, met with failure. By the time tetanus is clinically recognisable much of the toxin must already be in the nervous system, but still more may be coming into the blood from the organisms in the wound, and therefore antitoxin is worth giving. Dr. LESLIE COLE[2] who has treated 21 cases of tetanus in Cambridge advises injection of 200,000 units, intravenously. This is enough and the injections need not be continued, for observations on 4 of his patients have shown that after this dose the blood retains enough antitoxin for the next fourteen days to neutralise any toxin that may reach it. The toxin already in the nervous system, however, continues its evil work.

The fact that some patients recover shows that the body can eventually destroy this toxin, if it does not succumb to the secondary effects of the poisoning. These are chiefly exhaustion (and sometimes asphyxia) from the muscular spasms, inanition from the inability to take food, and hyperpyrexia. If these effects can be countered by symptomatic treatment, the patient may be kept alive until he can recover. Curare, with its classical action of blocking the impulse in the motor nerve just as it reaches the muscle, has been suggested as a suitable means of abolishing the spasms. COLE[2 3] tried it in three cases and found that it greatly diminished both the spasmodic tetanic contractions and the tonic rigidity between them, even in doses which were not large enough to abolish respiratory movements. That was encouraging, and were the curare action as simple as it at first appears it might be possible to push it further to produce complete paralysis, substituting mechanical artificial respiration for spontaneous respiration. Curare, however, is a mixed and variable product; it may contain poisonous ingredients as yet undefined, and there is a suggestion that its rigidity-reducing action in tetanus is a new and central action, not the peripheral one familiar to the physiologists. Prof. Florey[4] has therefore treated experimental tetanus in rabbits with the alkaloid curarine, which has the classical action only. It controlled the rigidity and the fits by producing its characteristic paralysis, and the animals had sometimes to be put in a modified Drinker's respirator. He suggested the use of a similar procedure in man. Dr. Cole, however, has in most of his cases used Avertin anæsthesia for the same purpose. It is simpler and much more familiar, and to judge from the case he reports in our present issue it is also effective. In discussing his 21 cases he points out that the well-known relation between prognosis and length of incubation period is remarkably precise: excluding patients over sixty, those with an incubation period of 7 days or more recovered, while those with an incubation period of less than 7 days died. By this criterion, the infant showing the disease at 6½ days of age should have died: but kept continuously under the influence of avertin for three weeks, and fed through a stomach tube, it recovered. It may be hoped that, unless adults are a great deal more intolerant of avertin than children are, this substance will do as much in the treatment of tetanus as curare was expected to do, and with less risk and uncertainty. That may help to save some of the severe cases, with short incubation periods, and should make the problem of feeding easy. The hyperpyrexia remains to be both explained and treated. It has been suggested that the tetanus toxin may reach and disturb the heat-regulating centre; if so, it may do likewise with the respiratory and vasomotor centres. So cold sponging or cold baths may be called for; a Drinker's apparatus or a Bragg-Paul pulsator should be available; and the pulse and blood pressure must, of course, be watched. It is not surprising therefore that Florey pled for the rapid transport of cases of tetanus to pre-arranged centres, where teams of people with equipment and experience are ready to deal with them. With the general practitioner would remain the important responsibility of recognising the disease at once, of knowing how much can be expected or hoped from modern treatment, and of getting his patient in the least possible time to a place where that treatment is available.

ACCIDENT PRONENESS

The modern tendency to think in terms of establishing and maintaining health, rather than of patching and repairing the inroads of disease, is nowhere better exemplified than in the activities of the Industrial Health Research Board—one of the few good things born of the war, by munition workers out of welfare. The fifteenth annual report[5] tells of many researches completed and in progress. The establishment of standards of physique for different grades of the community is an example; university students were found to be 2 inches taller than employed workers, 3½ lb. heavier, with greater muscular power; while unemployed men were 1 inch shorter than the employed, 7 lb. lighter, with much less muscular power. Mental and physical activity are closely associated, as also, nearly certainly, is physical health, although no reliable health data could be collected. London men excelled in height and weight, which fell away in passing north through Birmingham and Liverpool, by Leeds and Sheffield to Glasgow. Sedentary work seemed to recruit small men, and the heavy industries those of superior physique; but mechanisation may be expected to annul the demand for brawn and muscle. Nevertheless, creative effort is essential, if the best is to be got out of any man. Strength was found to decline with the approach of middle age; but no evidence was forthcoming about age variations in mental activity.

A result of studying industrial records, of great topical interest, has been the discovery of "accident proneness," an innate characteristic of some persons. This proneness obeys definite laws; it is found in one-quarter of the people, and results in this minority accounting for three-quarters of all accidents. Its laws hold good for accidents in the home and on the road, as well as in the factory—even for the chances of getting a foreign body in the eye. It is a personal phenomenon, independent of conscious action or blameworthiness. The accident prone are generally the least healthy and the world's worst workers; in industrial life they can be detected, and, by removing them from risk, the incidence of accidents may be greatly reduced. On the road, they are the hardened, bad drivers, and their elimination from those licensed to drive would reduce to 25 every 100 accidents that are occurring daily. Another important law relating to accidents is their liability to happen to the inexperienced: thus, in one instance,[6] an accident rate of 111 per 1000 workers of under six months of service fell away to only 8·5 for those of 10 to 15 years of service. Clearly avoidance of a high labour turnover conduces to a low accident-rate. There is known to be an optimum temperature, 67·5 F. at which fewest accidents occur, and exact information is now being sought as to the effect of lighting on the incidence of accidents. Indeed, accidents would appear to be as possible of control as other interferences with health. Study is being devoted to the influence of noise upon sickness absenteeism; it may increase the incidence of "nervous" cases. Pronounced individual differences have been revealed in psychological make-up; to some the unbroken uniformity of repetitive operations is a source of dissatisfaction; others experience no boredom and are content. But healthy and cheerful surroundings go far to minimise boredom and discontent; so also do such distractions as gramophone music, although the time and type of music must be suitable. Interest also attaches to a research into perseveration, of which an instance is afforded by the driver who continues to put his foot on the accelerator instead of the brake, because in his last car the brake was in the position of his present accelerator. These are only a few of many answers being sought to problems of everyday practical importance. As each answer emerges the rule is confirmed that it is not so much prosperity which gives health as that health brings prosperity.

ANNOTATIONS

PAVLOV

THE Neurological Congress brings many distinguished visitors to London, and among them we are glad once more to welcome Prof. Ivan Pavlov, now in his eighty-seventh year. Unknown outside Russia until the first decade of this century, his name has now become part of the vocabulary of physiology, inseparably linked with classical experiments on the digestive tract and the nervous system. To him we owe our knowledge of the mechanisms by which the digestive juices are secreted and adjusted in quantity and quality to the type of work they may be called upon to perform, and from him we have received the first glimmerings of the light which purely objective methods may throw upon the workings of the cerebral cortex. We could only detract from his work by attempting to give an account of it here; few are unacquainted with its broad outlines, and full translations of Pavlov's own published records are readily available. We may, however, attempt to understand the spirit in which it was done, and the principles on which it was based. Indeed, it is not difficult to summarise these in a single word, well known, well understood, often extolled, but seldom applied: "thoroughness."

His observations depended on the careful making of fistulæ at the time when asepsis was less commonly a feature of physiological experiments than it is to-day. He achieved success by adopting the most stringent surgical precautions before and during the operation, and by the care he bestowed upon his animals afterwards. This minute attention to detail characterised not only the execution of his experiments, but also their design. His operations were planned so that organs were made to yield accurate information under circumstances which differed as little as possible from the normal, and which allowed a transference of results, with little reservation, to the intact animal. The maintenance of nerve and blood-supply to the isolated gastric pouch is a case in point; Pavlov realised that unless this was in all respects a replica of the main organ, the operation was not worth performing. He would rather risk failure than abandon the ideal of perfection, and although few can hope to share his endowment of manual skill, we should sacrifice nothing of value if all were to adopt his methods of investigation. These are seen at their best in his work on conditioned reflexes, in which the success of each experiment depended on a rigid control of the animal's surroundings, even to the way in which it was approached by the experimenter. In these researches we discern not only elaborate care in design and execution, but the perfection of a new experimental method—a method whose conception signifies genius, and whose accomplishment bespeaks the self-confidence of one who has previously overcome apparently insurmountable difficulties. It is not easy to predict what its results will be, but it provides one of the few systematic means of access to that elusive entity, the mind.

But Pavlov's work—indeed, his whole life—means more than the addition of a few fresh facts to our store of knowledge. It is a corroboration of the faith of every scientist that forethought, tenacity of purpose and continued vigilance cannot fail to wrest from nature at least a few of her most closely-guarded secrets. In particular, it is an inspiration to the biologist, who is so often faced with a seemingly uncontrollable environment for his experiments.

INFANT FEEDING AND MORBIDITY

THAT the artificial feeding of infants has greatly improved in recent years—with increased knowledge of accessory food factors and the introduction of dried milk products with their superior keeping qualities—is not likely to be disputed. To what extent, however, artificial feeding can replace breast-feeding without detriment, not in a relatively few isolated cases but quite widely, is quite another matter. For an answer to that problem it is essential to have the evidence of growth curves and of sickness and mortality experiences. To the latter indices attention has been recently devoted by Grulee, Sanford, and Herron[1] and Grulee, Sanford, and Schwartz,[2] whose observations are drawn from 20,000 infants under the care of the Infant Welfare Society for Chicago for as long as nine months during the years 1924–29 inclusive. Nearly 10,000 of these infants were entirely breast-fed (with accessory feedings —e.g., orange juice, cod-liver oil); over 8,000 were partially breast-fed (comprising those who were entirely breast-fed for a time and then had to be weaned and those whose breast-feeding was complemented); and 1707 were artificially fed from the first.

The illnesses experienced in each group were recorded over the first nine months of life and classified in three broad categories, respiratory, gastro-intestinal, and other infections. From these data morbidity rates have been worked out for each separate month of age. The breast-fed were found to have sickness rates from respiratory infections mainly below those of the partially breast-fed. On the other hand, for the first four months of life the artificially fed have still lower rates, lower than those of either of the other groups, but they rise, somewhat abruptly, to a considerable excess in the 6th to 9th months of life. As might be expected, the breast-fed suffer substantially less than either of the other two groups from gastro-intestinal infections, but again the artificially fed show a relatively low incidence at 0–4 months and a considerable excess at 6–9 months. The same kind of feature is shown by the unclassified infections —viz., a lower incidence amongst the breast-fed, little to choose between the other two groups until the 6th month of life is reached. The general trend of these figures is an increasing incidence of sickness up to about the 6th month, followed by a declining rate in the totally and partially breast-fed, but a continued rise in the artificially fed. On the whole breast-fed have a clear advantage, especially in their relative freedom from gastro-intestinal disturbances, but the differences between the other two groups are not at all clear cut. It is difficult to see why the artificially fed should show to advantage in the first few months and be at a disadvantage in the later.

---

[1] Jour. Amer. Med. Assoc., 1934, ciii., 735.
[2] Ibid., 1935, civ., 1986.

The authors suggest that some immunity, declining with age, may be inherited from the mother and that breast milk may prolong this immunity beyond the sixth month; but this hypothesis cannot account for the lower rates amongst the artificially fed in the first 4 months of life. The comparison of the groups on the basis of their feeding presumes, of course, that they are broadly equivalent in other respects —e.g., their general environmental conditions. The authors do not provide any direct evidence on this point, though they show that their population is drawn from many different nationalities; only 10 per cent. are American.

It certainly seems impossible that the sickness experience can be representative of all infants, for the mortality is incredibly low. Amongst the 20,000 infants observed for nine months (or till death if earlier) there were but 227 deaths which gives a rate of only 11 per 1000. Sixty per cent. of these deaths were recorded in the small group of artificially fed infants, but in view of the extraordinarily low total rate it is difficult to accept this excess mortality as a characteristic of the feeding. Each group may be unrepresentative of the total experience from which it is drawn and perhaps not equally unrepresentative.

THE ACCURACY OF THE MEDICAL DIRECTORY

THAT admirable book of reference, Churchill's Medical Directory, should be accurate as a matter of service to the medical profession, and accuracy can only be ensured by regular communication to the Editor of the Directory, of changes of address. On page (272) of the current issue of THE LANCET will be found an alphabetical list of members of the medical profession concerning whose present address information is sought. We join with the Editor in hoping that the information will be promptly forthcoming.

Not only those individuals to whom application is made, but to the whole medical profession one word of warning is necessary. The maintaining of the accuracy of the Medical Directory in no way acquits a member of the medical profession from keeping the Registrar of the General Medical Council informed of any change in his residence. From time to time an official inquiry is sent to his registered address, and if this is unanswered his name appears in an official list of uncommunicated addresses published at definite intervals in our own columns. Failing reply to either of these his name is erased from the Medical Register under Section 14 of the Medical Act, 1858, and he loses all the privileges of registration under that Act. No reply to the Editor of the Medical Directory relieves a member of the medical profession from the responsibility of immediate response to any inquiry from the General Medical Council. The Medical Directory is an unofficial list of first value for reference to the medical profession, but the Medical Register is the official list, and it must be made plain that a member who finds his name in the list issued by Churchill is not absolved from replying to the General Medical Council.

POST-OPERATIVE CIRCULATORY LESIONS

AN attempt to throw light on post-operative circulatory lesions by radiography has been made by J. Frimann-Dahl.[1] First of all diaphragmatic movements were studied radiologically after abdominal operations in 20 cases. This investigation showed that the excursion of the diaphragm is generally much diminished, especially when the incision has been made in the upper part of the abdominal wall; but that normal movement returns in from one to twelve days. The next step was to study the rate of the venous circulation, which was estimated by means of intravenous pyelography, following the injection of Per-abrodil into the saphenous vein. Bed rest, except in thyreotoxic cases, was found to cause a definite retardation in the flow of blood. After operations, especially those frequently followed by thrombosis, the venous blood stream was mostly found to be very slow. Sometimes the blood coming from the saphenous vein flowed in a retrograde direction down the femoral vein, indicating almost complete stasis. In one such case the femoral vein was so dilated that it appeared to be under considerable tension and thrombosis was evidently imminent. Considering the causation of post-operative venous stasis Frimann-Dahl suggests that the chief factors are post-operative meteorism and muscular inactivity. The retardation of the venous circulation tends to last throughout the period of bed rest and cannot therefore be due primarily to diaphragmatic paralysis, since this is much more transitory and is often seen to be diminishing while the venous stasis is increasing. The flow of blood in the lower extremities may be accelerated by raising the foot of the bed, by massage, by active movements of the leg muscles, and by the inhalation of carbon dioxide; any of these methods may therefore be useful in the prophylaxis of venous thrombosis. The minute study of 14 patients with post-operative pulmonary embolism was also undertaken. Small emboli studied in serial radiograms were found only to produce transitory changes; those of larger size produced definite infarcts of triangular or circular outline usually situated at the base of the lung. Pleural effusion was frequently seen and adhesions obliterating the costo-phrenic angle proved to be a common sequel.

ALCOHOL AND ROAD ACCIDENTS

Mr. Hore-Belisha, Minister of Transport, asked the British Medical Association at the beginning of the year to give him its observations on the place of alcohol in the causes of road accidents. The Association appointed a special committee under Dr. W. G. Willoughby, and its report has just appeared.[1] The committee concentrated on small or "subintoxicant" doses of alcohol, less than would be likely to bring a motorist into the dock and far less than would cause social drunkenness. It has perforce relied on indirect evidence: statistics of accidents in which the question has been raised of whether the driver was under the influence of drink, and experiments on the effect of alcohol upon the faculties—judgment, memory, reaction, and muscular coördination—which are the foundation of safe driving. It quotes the Alcohol Committee of the Medical Research Council for the statement that alcohol is a narcotic and impairs judgment, concentration, self-criticism, and the power of estimating risk. It therefore leads persons to take risks and make rapid decisions less judiciously than they otherwise would. Impairment of concentration and reasoning power has, the committee point out, been established by physiological experiment. The driving of a motor car involves a succession of highly skilled muscular movements which depend on rapid and accurate coördination between the hands, eyes and feet. According to the M.R.C., the speed with which

[1] Brit. Med. Jour., July 27th, 1935, Supplement, p. 57.

the gaze is directed to fresh objects is diminished by alcohol. Speed and accuracy of hand movement have been shown by typewriting tests to suffer, and the coördination required in rifle-shooting and mountaineering is impaired. Alcohol disappears slowly from the blood, and substantial amounts remain in the blood even several hours after a moderate quantity of drink has been taken. The committee conclude that three ounces of whisky will affect the driving capacity of many persons some hours afterwards, and will make them think they are driving better than usual while really they are less efficient. These findings are no surprise to persons with any training in physiology, but may be news to laymen and lawyers. Besides indicating a possibly fertile cause of accidents, they suggest that the present law is not being administered as the facts demand. Under the Road Traffic Act a motorist is culpable who is incapable through drink or drugs of having proper control of his vehicle. This provision will cover the motorist who is not nearly drunk in the social or police-court sense, but its application is a matter of opinion. The subject was threshed out fairly fully at the Medico-Legal Society last month[2] when discussion indicated that before a motorist is likely to be convicted he must show some fairly obvious symptoms. Many physiological authorities regard him as a dangerous motorist even when he is apparently sober, simply because a minimal quantity of alcohol will impair his judgment of speed and distance, his visual acumen and his reaction-time, the factors which the National Institute of Industrial Psychology regard as essential in a driver's safety or danger. It is not likely that police surgeons and courts will give the Act the drastic interpretation which the facts suggest, because incapacity must be proved as a fact, and individuals differ so much in their initial skill and their reaction to alcohol. Better results should be obtained by energetic publication to motorists and pedestrians of the danger of little drinks.

A POISONED KIDNEY

A QUANTITATIVE study of renal injury due to acute poisoning by bichloride of mercury is recorded by Freyberg and Lashmet.[3] The patient, a woman aged 20, took 1·5 g. of the poison, and though much of it was vomited, enough was retained to cause severe gastro-enteritis for several days. Within a few hours of ingestion there was much albumin, with large numbers of renal epithelial cells and renal tubule casts in the urine, and in 7½ hours the urea clearance was down to 34 per cent. of the normal. The clearance diminished to 10 per cent. between the second and ninth days, and thereafter improved slowly but steadily, reaching the normal again 3½ months after the mercuric chloride was consumed. Impairment of the capacity of the kidney to form urine of high specific gravity and of the capacity to excrete phenolsulphonephthalein was demonstrated, and it is interesting to note that the quantity of albumin, casts, and renal epithelial cells passed in the urine diminished considerably before there was any great improvement either clinically or in the capacity of the kidneys to excrete, or to form high concentrations of, the natural constituents of the urine. The treatment of the renal lesion consisted in the daily administration of 5000 c.cm. of fluid intravenously either as physiological saline or as 5 per cent. glucose. Thus stimulated, the kidneys excreted the water and evidently the non-protein nitrogen with it, for the non-protein nitrogen of the blood was but slightly increased. Moreover, no ill-effects were observed which could be ascribed to the intravenous administration of fluid, there being for example no œdema. It should be remembered however that in acute nephritis not due to metallic poisons, large volumes of fluid usually fail to increase the urine flow and are retained in the tissues. Thus the treatment which has met with success in a case of mercurial poisoning may prove dangerous if applied to other renal lesions.

Porter and Simons[4] have described the therapeutic effects of gastric lavage, alkalis and intravenous administration of 1000 c.cm. of saline 12-hourly so long as vomiting persists. Of 46 cases of mercurial poisoning so treated 43 recovered. The plasma non-protein nitrogen was over 50 mg. per 100 c.cm. in the three fatal cases and under 50 mg. in all those that recovered.

C S M M G

The new Register (1935) of the Chartered Society of Massage and Medical Gymnastics contains the names of over 9,500 members, of whom more than 600 are masseurs. When this society came into existence as a chartered body in 1920, as the result of the fusion of the Society of Trained Masseuses and the Institute of Massage and Remedial Gymnastics, its total membership was 3,640. The great and continuing growth of the society in the last fifteen years has been due to the increasing recognition of the value of physical therapy as an ancillary to medical and surgical treatment, when under proper control, and it sufficiently refutes the occasionally heard assertion that this branch of therapeutics has been losing its usefulness since the war years. These registered members have passed through a comprehensive and practical two years' course of education in massage and medical gymnastics, including training in hospitals, and have been accredited by searching examinations. Most of them hold additional qualifications in medical diathermy and light therapy, which entitle them automatically to admission to the Society of Apothecaries' Register of Biophysical Assistants. Certificates are granted also after training and examination in medical electricity, light and electrotherapy, medical hydrology, and for teachers of massage and medical gymnastics, medical electricity, and medical hydrology. The Register of the Chartered Society indicates these various distinctions in each case. It is supplied free of charge to medical practitioners anywhere on application, thus providing them with the names and addresses of members practising in all districts. All these members have pledged themselves not to undertake any case except under the direction of a registered medical practitioner, not to advertise except in recognised medical and nursing papers, and not to sell goods to patients in a professional capacity nor to accept secret commissions on the sale of goods. A high standard of professional honour has thus been attained, and the sweeping away of the evil practices of last century has gained for the Chartered Society the confidence of the medical profession and the general public. There has thus been made available for medical practitioners a service of highly trained and trustworthy assistants in physical therapy, and it is a reasonable hope that they will be employed in preference to other exponents of this therapy who have not accepted such a course of training, nor bound themselves not to compete with the medical profession. The evils of uninstructed and uncontrolled physical therapy can only be overcome if members of the Chartered Society receive the full support of medical practitioners; they depend for their livelihood on such coöperation which they have set themselves to merit. The annual congress this year of the Chartered Society is to be held in Harrogate from Sept. 18th to 21st, and its scientific meetings are open freely to medical practitioners on presentation of their visiting cards. Among the subjects to be discussed are: the treatment of hips and spines at American orthopædic clinics; functional disorders and malingering; fibrositis; short-wave therapy; bone regeneration; and the spa treatment of rheumatism. All these topics will be introduced by medical experts.

CATARACT FOLLOWING THE USE OF DINITROPHENOL

ANYONE who has followed recent medical writing on the subject must be aware that opinion on the place of dinitrophenol and allied compounds in the treatment of obesity is sharply divided. Some of the arguments were stated briefly in these columns about a year ago.[1] It was admitted that certain of the nitrophenols are powerful stimulants of katabolism and are therefore bound to be effective in reducing flesh. At the same time, it was pointed out that unpleasant symptoms and even death had followed the indiscriminate use of these drugs, and readers were reminded that the physician commands no means of lowering a basal metabolic-rate which has been raised too far. There is still no general agreement whether the undesirable symptoms encountered are specific toxic effects of the drug, or simply expressions of excessively high metabolism, although it is not easy to attribute some of the recorded symptoms to the latter. Meanwhile two papers from San Francisco[2] provide a strong argument in favour of giving up the use of these drugs for the present. They record six instances of cataract occurring during the treatment of obesity with dinitrophenol; the patients were women in a period of life when spontaneous cataracts are rare; the ages in five being 50, 36, 39, 40, and 30; the cataracts were bilateral and rapidly progressive, becoming measurably worse in periods measured by days and leading in more than one instance to almost complete blindness within a month. Two of the patients had received the drug under strict medical supervision, a third had treated herself, and in the remainder no particulars are given. The authors of the papers urge that "further use of dinitrophenol should be discontinued, pending further study on its secondary systemic effects." It is possible, though very unlikely, that the cataract in these cases was due to some factor other than the treatment. A less improbable explanation is that the particular preparation of dinitrophenol was contaminated with some unknown toxic substance. But with the eyesight of a patient at stake, however slight the risk, the duty of the physician is clear.

Our previous article concluded with the following question: "Is it justifiable, in dealing with a condition which almost always responds readily to a little wholesome discipline (i.e., dietetic restriction), to employ instead a drug of unquestioned potency but uncertain toxicity?" The tragic accidents now described should resolve any lingering doubts about the answer.

AIR RAID PRECAUTIONS

THE first of a series of handbooks on Air Raid Precautions has just been issued by the Home Office. It is entitled No. 2—"Anti-gas Precautions and First Aid for Air Raid Casualties." (H.M. Stationery Office, 6*d*.) The general preface to the series of handbooks emphasises that their production is a measure of precaution only, and does not arise from any belief that war is imminent. This particular handbook has been written for those who would be engaged on first-aid services for the civil population, and especially members of the St. John Ambulance Brigade, the St. Andrew's Ambulance Association and the British Red Cross Society. It deals with the gases and other chemical agents which might be employed in war, and indicates the probable methods of their use. No suggestion is made that there are new gases of exceptional potency. Two types of respirator are described: the general service respirator as issued to the Navy, Army and Air Force, and a simplified pattern designed mainly for persons employed in civil air raid services. The last chapter sets out the organisation of a combined first-aid and decontamination centre for members of the public. In addition to these handbooks the Home Office promises a series of memoranda dealing with the organisation of public air raid precautions by local authorities.

MALIGNANT DISEASE OF THE GALL-BLADDER

Is the possibility of future malignant change a good reason for persuading a patient with gall-stones to consent to operation? Dr. John F. Erdman,[1] reviewing his experience of 525 gall-bladder operations, concludes that it is not. His argument is that, considered statistically, the patient's chance of dying as a direct result of his operation is higher than his chance of subsequently developing cancer in the gall-bladder. Among his 525 cases there were 15 deaths—a mortality of 2·8 per cent.—but only 6 (1·1 per cent.) with malignant change. Erdman would have us, therefore, lay stress rather on the likelihood of chronic ill-health or of repeated colic than on the possibility of cancer. C. F. W. Illingworth,[2] on the other hand, maintains that the danger of cancer developing is quite appreciable, and that, for the prevention of future malignancy, the benefits of excision of the gall-bladder in all cases of calculus cholecystitis far outweigh the risk. The figures he quotes for the incidence of carcinoma following gall-stones—viz., 7–8 per cent. in 500–600 cases (Riedel), and 81 carcinomas in 592 autopsies on patients with gall-stones (Fawcett and Rippelman)—are very considerably higher. In all 5 of Erdman's cases in which operation revealed carcinoma of the gall-bladder, a stone or stones or biliary sand was also present; and in the single case of sarcoma there were five stones. (Sarcoma is, of course, a very remote possibility; he found only 30 cases on record.) Of Illingworth's 50 cases of malignant disease 31 definitely had gall-stones; in 7 they were undoubtedly absent; in 12 there was no record of presence or absence.

Illingworth is convinced that carcinoma of the gall-bladder is preceded in every case by cholecystitis. The patient will therefore tend to give a typical gall-bladder history, with "flatulent indigestion, pain below the costal margin, and occasional attacks of biliary colic." Nausea he found to be a constant symptom. The diagnosis of malignancy is very unlikely to be made until the abdomen is opened, since only the presence of metastases can give definite pre-operative evidence. Erdman says that jaundice does not develop unless the liver is already invaded. All his cancer patients had the typical pain, in the usual site and with typical radiation, and they later developed digestive disturbances. In one case, operated on for a perforation of the gall-bladder, a suspicion of malignancy at the time of operation was not confirmed by the pathologist's report, but in 7½ months secondary deposits had caused a recurrence of pain and jaundice, and nothing could be done. In the solitary case of sarcoma a definite lump was palpable in the right hypochondrium. Cholecystectomy was performed with ease; the wall of the gall-bladder was 1½ in. thick, and there were present in it several large nodulated masses of a livid to purplish hue. While Erdman thinks that papillomata may be a precursor of cancer, Illingworth holds that they bear no important relationship to one another. In the cholecystogram papillomata show up as patches of decreased density; one such case is illustrated in Erdman's paper. He is strongly in favour of cholecystectomy as the operation of choice in diseases of the gall-bladder. The danger of missing a carcinoma or papilloma in the simple drainage operation is one of his main reasons for this opinion. In his own series, cholecystectomy was performed 522 times, and cholecystostomy 3 times.

[2] Brit. Jour. Surg., July, 1935, p. 4.

Illingworth recognises four pathological types of carcinoma of the gall-bladder—the scirrhous carcinoma, which is the common type, the papillary, the mucoid, and epithelioma (very rare). This last type—an example of a squamous-cell growth occurring in a columnar-cell epithelium derived from ectoderm—is to be regarded as arising by a process of metaplasia, the columnar-cells reverting to primitive form and subsequently assuming squamous characters.

The Duke of Kent has appointed Dr. A. E. Gow, physician to St. Bartholomew's Hospital, to be physician in ordinary to his household.

Sir George Chrystal, secretary to the Ministry of Pensions, has been appointed permanent secretary to the Ministry of Health, in succession to Sir Arthur Robinson. After fifteen years at the Health Ministry Sir Arthur has accepted the chairmanship of the Supply Board, newly reconstituted with a view to the needs of the Defence Services.

INDEX TO "THE LANCET," VOL. I., 1935.

THE Index and Title-page of Vol. I., 1935, which was completed with the issue of June 29th, is now in preparation. A copy will be sent gratis to subscribers on receipt of a post-card addressed to the Manager of THE LANCET, 7, Adam-street, Aldephi, W.C.2. Subscribers who have not already indicated their desire to receive Indexes regularly as published should do so now.

CENTRAL LONDON THROAT, NOSE, AND EAR HOSPITAL.—Princess Louise, Duchess of Argyll, recently laid the foundation stone of the nurses' home at this hospital of which she is president. The estimated cost of the new building is £30,000, and £12,000 has already been subscribed. The site has been provided by an anonymous friend who contributed £2000 for the purpose.

Lt.-Col. G. F. Rudkin, D.S.O., from R.A.M.C., to be Col.

ROYAL ARMY MEDICAL CORPS.

Majs. to be Lt.-Cols.: W. P. Croker and E. W. Wade, D.S.O.

Capt. R. A. Bennett to be Maj. Jan. 29th, 1935. (*Substituted for notification in the Gazette of Feb. 8th, 1935*, vide THE LANCET, Feb. 16th, 1935, p. 398.)

REGULAR ARMY RESERVE OF OFFICERS

Maj. Sir Robert G. Archibald, C.M.G., D.S.O., M.D., having attained the age limit of liability to recall, ceases to belong to the Res. of Off.

ARMY DENTAL CORPS

Lt.-Col. W. M. Ferguson, having attained the age for retirement, is placed on ret. pay.

Maj. G. F. Charles to be Lt.-Col.

Maj. (prov.) A. H. Kay reverts to the rank of Capt.

TERRITORIAL ARMY

J. J. M. Brown (late Cadet, Edinburgh Academy Contgt., Jun. Div.), O.T.C., to be Lt.

Lt. A. C. Armstrong to be Capt.

G. Carruth (late Offr. Cadet, Queen's Univ., Belfast, Contgt. (Med. Unit), Sen. Div., O.T.C.), to be Lt.

ROYAL AIR FORCE

MEDICAL OFFICERS AS PILOTS

An amendment to the King's Regulations and Air Council Instructions provides that a medical officer who has qualified as a pilot may, when facilities exist at the unit to which he is posted and provided he is medically fit, keep himself in flying practice. Unless, however, he has flown solo during the preceding three months and has had *solo* flying experience in the type of aircraft which it is proposed to fly, the C.O. will ensure that he receives adequate dual instruction in that type before he flies solo.

Wing. Comdr. R. W. Ryan to Central Medical Establishment for duty as President of the Central Medical Board.

Dental Branch.—H. M. G. Williams, L.D.S., is granted a non-permanent commission as a Flying Officer.

RESERVE OF AIR FORCE OFFICERS

Flight Lt. P. J. Nyhan relinquishes his commission on completion of service.

INDIAN MEDICAL SERVICE

Capts. to be Majs. (provl.).—Bt. Maj. M. S. Gupta, S. P. Joshi, R. Linton, and H. W. Mulligan.

The Commander-in-Chief in India has made the following appointments:—

Lieut.-Col. P. S. Tomlinson, D.S.O., as D.A.D. of Medical Services for Mobilisation, Northern Command.

Lieut.-Col. G. F. Allison, M.C., as D.A.D.M.S., Northern command.

Major-General J. F. Martin, C.B., C.M.G., C.B.E., is granted two months' leave from August 7th, when he will vacate his officiating appointment as Director of Medical Services in India. At the expiry of his leave he will vacate his substantive appointment of D.D.M.S., Western Command.

Dr. A. H. L. Thomas has been appointed Admiralty surgeon and agent for London district No. 15 (Westminster, Victoria, &c.).

PROGNOSIS

A Series of Signed Articles contributed by invitation

LXIII.—PROGNOSIS OF HALLUX VALGUS AND HALLUX RIGIDUS

Hallux Valgus

UNCOMPLICATED hallux valgus is a painless static condition like genu valgum, and may be present for many years without symptoms. It is the bursitis which so often supervenes that causes pain, and when inflammation or even suppuration are added, the condition becomes extremely disabling. Over-riding toes may also cause pain by producing troublesome corns and callosities. We must therefore be cautious of advising operative treatment in the absence of pain unless, as sometimes happens in young women, it is desired purely with the object of improving the appearance of the feet. Palliative treatment is, on the whole, ineffective and the proprietary bunion pads are of little use. In an early or mild case it is sometimes worth while trying faradism to the short muscles of the foot and a plaster-of-Paris splint to be worn at night, but the mechanics of the condition demand a shortening of the bony pier on the inner side of the foot and any treatment that fails to achieve this is rarely successful. If operation is advised it should be restricted to such toes as cause pain, and an infected bursitis must first be cleaned up, even though this may necessitate a preliminary ten days in bed. It probably matters very little whether the head of the metatarsal or base of the first phalanx is excised so long as enough bone is removed to allow of full correction. The toe is held in position for ten days after operation by some form of semi-rigid bandage, and at the end of that time the patient may begin to walk. It will usually be three weeks from the operation before an ordinary shoe can be worn, and progress is naturally quicker in unilateral than bilateral examples.

There is a great tendency for patients to try to spare the inner border of the foot by walking on its outer edge, and this is the commonest cause of failure after operation. Every patient should be told he *must* bear weight on the inner border of the foot lest he gives himself a secondary metatarsalgia. A. Blundell Bankart has advised an *outside* wedge of ¼ in. after operation, and this should be a standard post-operative precaution.

Patients vary in the duration of convalescence, which occasionally is very slow. This is often because they are not made to realise the necessity of early weight-bearing on the operated toe, and are allowed to hobble around for months on the outer borders of their feet, courting secondary metatarsalgia and usually getting it. A determined or understanding patient will recover very rapidly, and I recall a girl of 19 who was in the semi-final of a tennis tournament less than four months after a bilateral operation, and an out-patient sister who returned to her exacting duties three weeks after a similar operation.

Operation for hallux valgus has an undeservedly bad reputation, and results are much better than is often believed. The two fundamental secrets of success are (1) to remove enough bone, and (2) to get the patient to bear weight early on the operated toe.

Hallux Rigidus

Hallux rigidus is an entirely different condition. It is not a static deformity but a degenerative osteo-arthritis. It occasionally follows an injury, but is much more often like (hallux valgus) a manifestation of the flattening foot which (in straight-toed individuals) induces an osteo-arthritis by the repeated trauma of phalanx and metatarsal being crushed against one another. The earliest manifestations are restricted dorsiflexion and the development of dorsal osteophytes. Dorsiflexion of the big toe takes place every time we lift our heel to take a step forward, and this becomes painful or impossible. Palliative treatment consists in trying to eliminate this movement of the toe by the insertion of a steel plate in the sole of the shoe. It removes the natural spring from walking, and is rarely a conspicuous success. Splints worn inside the shoe are more efficient but less comfortable, and operation is frequently demanded for the relief of pain. Osteo-arthritis elsewhere is often best treated by arthrodesis, but the mechanics of walking make this procedure unsuited to the metatarso-phalangeal joint. It is therefore proper to excise the head of the first metatarsal with its peripheral osteophytes, and to leave the base of the first phalanx alone.

In contradistinction to hallux valgus, the big toe is sometimes stiff after operation, but there is usually a great relief in spite of this, and a patient is generally able to resume activities and even games which were previously impossible.

ERIC I. LLOYD, M.B., F.R.C.S.,
Orthopædic Surgeon to the Royal Northern Hospital, and Surgeon to the Hospital for Sick Children, Great Ormond-street.

TOXICITY OF INDUSTRIAL SOLVENTS.—At the request of the Home Office, the Medical Research Council have undertaken to promote investigation into the question whether various volatile substances might injure the health of workers using them under industrial conditions. To assist and advise them in this matter, the Council have appointed the following special committee. Sir Joseph Barcroft, F.R.S. (chairman); Dr. J. C. Bridge; Prof. A. J. Clark, M.D., F.R.S.; Mr. A. G. Green, F.R.S.; Prof. J. A. Gunn, M.D.; Prof. E. H. Kettle, M.D.; Dr. H. B. Morgan; Mr. J. Davidson Pratt; Mr. D. R. Wilson, C.V.O., C.B.E.; and Sir David Munro, F.R.C.S.Edin. (Secretary).

SPECIAL ARTICLES

BRITISH MEDICAL ASSOCIATION

PROCEEDINGS OF THE REPRESENTATIVE BODY

(*Concluded from p. 212*)

The Services

In proposing the adoption of the remainder of the Council's report under "Naval and Military," Dr. F. W. **Goodbody** accepted a request by Torquay (Dr. E. **Ward**) asking the Council to consider the adequate representation of the Home Defence Forces on the Committee. He said that the Admiralty appeared to be applying satisfactorily the terms of service recommended in the Warren-Fisher report and that the Naval Medical Service was worthy of support by the Association. Conditions in the R.A.F. Medical Service seemed to be much the same; owing to expansion, civilian doctors were being employed, and their conditions would have to be watched very carefully. The Directors-General of the two senior services were made Rear-Admiral and Lieutenant-General respectively, on appointment, but the Director-General of the R.A.F. Medical Service had not yet been made an Air Vice-Marshal.

Rear-Admiral A. R. **Thomas** said that the Admiralty had faithfully tried to apply the recommendations of the Warren-Fisher Committee, and substantial benefits had been obtained. Plenty of applications, of high standard, were being received, and he had no hesitation whatever in advising a man to join this service. The new regulations should be given a chance.

Dr. **Goodbody** moved a motion expressing satisfaction with the R.A.M.C., saying that valuable concessions had been secured from the Army Council and criticism should be withheld at the present time. An officer could now retire after five years' good experience with a fairly substantial grant; further, on medical matters, the medical officer was to be allowed access to the Army Council, and the Director-General could go straight to the Secretary of State. There was a great shortage of R.A.M.C. Territorial officers, concluded Dr. Goodbody, and he hoped that representatives would help to remedy this. After strong reasoned support from Col. J. W. H. **Conway**, Col. C. H. H. **Harold**, and Dr. G. F. **Gibbons**, the meeting passed the motion. The **Chairman** congratulated the Committee on a brilliant piece of work. The report under "Indian Medical Services" was also approved, on the motion of Sir **Richard Needham**, who explained how this service had been reconstituted.

Hospitals

Dr. **Peter Macdonald** moved the adoption of the Annual Report on Hospitals, and also—

> That para. 5 of the Summary of Conclusions and Recommendations of the Association's Report on the Problem of the Out-patient be amended by the addition of the following :—All patients presenting themselves at hospital for treatment without a doctor's letter should be examined by a registered medical practitioner on the Staff of the hospital. Such cases will fall into two categories : (1) Emergency cases ; (2) Non-emergency cases, and should be dealt with as follows : *Emergency cases* should receive appropriate first treatment, and if no special hospital treatment is required, be referred back to their own doctors. The term "own doctor" means the doctor from whom the patient would ordinarily obtain domiciliary treatment. *Non-emergencies*, unless they require special treatment which can be obtained only at hospital, should be referred back to their own doctor without receiving advice or treatment."

[Para. 5 of the Conclusions and Recommendations at present reads : "Further checks and safeguards should be established at all voluntary hospitals before treatment is undertaken at the out-patient department."]

Southampton, however, wished to delete :—

> "*Non-emergencies*, unless they require special treatment which can be obtained only at hospital, should be referred back to their own doctor without receiving advice or treatment," and to substitute :—"*Non-emergencies*, except the necessitous poor, shall be referred back to their own doctor."

In the absence of its representative and on the vigorous opposition of Dr. **Macdonald**, the meeting rejected Southampton's amendment, which, said Dr. Macdonald, would only irritate all concerned and was a retrograde step in the Hospitals' Policy, which considered that there was no need to differentiate the necessitous poor. Dr. **Stratford** proposed the omission of the words "unless they require special treatment which can be obtained only at hospital"; for who, he asked, was to decide what that was and to estimate the abilities of any given general practitioner ?—Dr. H. D. **Woodroffe** (Oxford) added that there was no hurry about these patients, who could wait for proper reference by their doctor and who should be discouraged from dropping into hospitals for special treatments.—Dr. **Wand** (Birmingham) said that the words "obtained only at hospital" accurately defined "special treatment," and thought it important to find a form which hospitals would accept.—Dr. E. R. C. **Walker** and Dr. F. **Gray** supported the amendment, proffering their experience in Aberdeen and at the Bolingbroke Hospital, Wandsworth.—Dr. **Macdonald** failed to persuade the meeting that there was nothing much in the amendment after all, though he pleaded for the countryman who came a long journey from a district where no specialist treatment was available.

As the result was 65 votes to 50 in favour of the amendment, there was no two-thirds majority as required to alter the policy of the Association. The amendment was put as a substantive motion, with this warning, and the necessary majority was then obtained.

Dr. **Macdonald** then brought forward a motion reiterating that consultants should use the second page of the Association's model hospital letter in writing to doctors whose patients had come without a letter.—Birmingham objected again, as it had last year, and Dr. **Wand** moved :—

> "That the recommendation be amended by the deletion of the words 'second page of the form when returning the patient to his own doctor,' and the substitution therefor of the following :—
>
> '..................Hospital.
> ....Date.
>
> Dear Dr..................
> I have to-day seen your patient..................and am of the opinion that he, or she, is suffering from..................
> I have therefore (1) admitted him/her.
> (2) Ordered the special appropriate treatment.
> (3) Given emergency treatment.
> (4) Referred him/her back to you.
> Yours faithfully,
> ....'
>
> "That the Association take steps to make available to hospitals a supply of the form referred to in the foregoing Motion."

He could not see, he said, what confusion could be caused by the use of two forms. The use of the form proposed would educate young house-surgeons in the B.M.A. policy.—Dr. J. A. BROWN was amazed that this resolution should have had to be brought up again after being passed by a large majority last year. The second page of the model form was practically a blank sheet and not in any way comparable with the form proposed.—Dr. A. MACCARTHY pointed out that the form Birmingham wanted to use was for cases where the patient brought no letter with him and so the consultant had no "second page" to use.—Dr. MACDONALD thought Birmingham's form an excellent one, but the other was already in wide use. Mr. McADAM ECCLES regarded it as disastrous to try to upset the quarter of a million forms already in circulation, and said Birmingham could have its own form if it liked. Birmingham gained support from Dr. GRAY (Wandsworth) and Dr. KEITH GIBSON (Kensington). The London Panel Committee, said Dr. GIBSON, and the London Public Medical Service had gone to the trouble of printing their own forms, as they felt they needed more than the B.M.A. form. They convinced a large majority of the representatives, and the amendment was carried.

Dr. HOWIE WOOD (Isle of Wight) proposed, and agreed to refer to Council :—

"That the Representative Body is of opinion that when members of the honorary staff of a voluntary hospital receive payment for services rendered to a public authority, or receive monies in the form of a staff fund in connexion with their work under a contributory scheme, their status as members of the honorary staff of the hospital should not be affected; and that the Council be instructed to consider what, if any, amendments to the Hospital Policy of the Association are necessary in order to give effect to the foregoing."

The Supplementary Report under "Hospitals" brought a long statement from Dr. MACDONALD, as it dealt with provident schemes for middle-class persons. Last year, the Council was asked to arrange for a payment to the general practitioner to be included in these schemes, and it regretfully reported itself unable to do so. Schemes for specialist services seemed to rest on a much more secure actuarial basis than could be provided for general practitioner attendance, and it would prove almost impossible to define a "general practitioner condition." There were, said Dr. Macdonald, no data on the costs of "g.p." treatment. The Association was going to call a conference to consider the establishment of a permanent central body to coördinate the activities of local provident associations; the subject could then be raised once more.

Manchester wished to refer the matter back to Council, because some general practitioners were already being paid.—Dr. R. BOYD said that if the scheme were limited to specialists the principle of free choice of doctor must be infringed. Several bodies in Manchester and other towns had paid general practitioners for years. He did not wish, he concluded, to go back to his division and say that the B.M.A. had again let down the general practitioner. —Mr. McADAM ECCLES thought the day had not yet come, though he hoped it soon would; meanwhile investigation must go on—there was great need for grants-in-aid towards serious illnesses demanding specialist services.—Dr. WATERFIELD asked Dr. Boyd to withdrawn this motion, as the matter had been thoroughly studied and the Council had done all it could do at present.—Dr. KEITH GIBSON could not follow the extent to which cases and their doctors might go to hospital under provident schemes.—To which Dr. MACDONALD replied that the answer could only be given by an individual provident scheme. Reference back to Council, he added, could only have the same result again; the Representative Body must either approve the report or withdraw its approval of last year. Manchester's motion was, however, carried by a small majority (45–39).

Medical Benevolence

Dr. E. E. BRIERLY presented the Council's report under this heading, pointing out that a number of children in Scotland were being educated at day schools in addition to the 56 Foundation Scholars maintained at Epsom. There had been an increase in subscriptions of over £700, apart from a windfall of £925, the residue of the late "Dr. Cooke Appeal Fund." The year before the establishment of the Charities Fund and Committee the sum of £1616 had been subscribed for medical benevolence; this had increased to over £7000, but was still quite insufficient. —Dr. LEWIS GLOVER (Hampstead) said the panel committees were coming along splendidly.

Miscellaneous Motions

Dr. WATERFIELD proposed three motions for Kingston :—

"That it is the opinion of the Representative Body that instruction in anti-chemical warfare measures, should be given to medical students.

"That similar instruction should be available for post-graduates.

"That in view of the necessity for educating the public in measures of protection against chemical warfare, the B.M.A. should ask for the coöperation of its members."

The CHAIRMAN said that he and Dr. Anderson had recently been invited to a conference on these matters at the Ministry of Health, which was fully alive to the problem and to the value of the Association's organisation for disseminating knowledge.—Dr. F. C. GITTINGS invited any member to go to Portsmouth for a week's anti-gas course free, and Dr. N. WEST-WATSON described the campaign of the St. John Ambulance Brigade and British Red Cross. Dr. E. CASSON emphasised the danger of alarming the general public and recommended the example of the Dutch medical profession's "war prophylaxis committee." Kingston's motions were carried.—Dr. A. T. JONES (Brecknock) proposed that the Council should consider means of opposing and preventing all chemical warfare. To get rid of war, said Dr. H. CAIGER (Sheffield), was the duty of this generation, just as the nineteenth century had got rid of slavery. The meeting cordially agreed.

Sheffield found the working of the Workmen's Compensation Act very unsatisfactory as regards miners' nystagmus, and Dr. CAIGER gave a full statement of the problem, emphasising the anxiety neurosis involved, the high incidence in miners over 50, the small amount of disablement, and the difficulty of distinguishing those disabled from those not disabled. The first result of the Act, he said, had been injustice to the employers, and their reaction had brought hardship to the men. The medical profession could solve this difficult problem by insisting on better lighting in the pits, the provision of suitable work for patients and more accurate certification. It had been shown that miners with slight nystagmus could go on working with better light and be cured. Mr. BISHOP HARMAN supported the resolution, which was carried, asking the Council to initiate action on the matter.

Dr. B. H. Pain, for Tunbridge Wells, urged the importance of getting medical men on the boards of local authorities and asked the Council to consider the establishment of a fund to help medical candidates at local elections. His eloquent appeal was supported by Dr. W. Asten, who nevertheless said that Bournemouth objected to the fund, and asked the Council instead to consider the wisest procedure to ascertain the candidates most fitted. The amendment was feelingly seconded by Dr. W. G. Willoughby (Eastbourne), who had seen many medical members on local authorities. He thought a fund would greatly reduce the doctor's chance of election, as the candidate must represent a district and not a special interest. Dr. A. B. Murray also urged that medical men should come forward on their own merits and not as sectional representatives. Support on these lines came further from Dr. H. Robinson (Kensington), Dr. Middleton Martin, and Sir Henry Brackenbury. This weight of argument drowned the faint appeals made for the impecunious candidate, and Tunbridge Wells withdrew their motion in favour of the amendment brought forward by Bournemouth.

Torquay (Dr. Ward) proposed :—

> That in view of the fact that certain non-nationals are being admitted to the Medical Register after only an abbreviated course of study in the British Isles, and are coming into competition with our own practitioners, the Representative Body instructs the Council to press for the enforcement of the three years' mimimum course of study in recognised medical schools before non-nationals can be admitted to the Medical Register of the United Kingdom.

He quoted figures in support of his division's apprehension and was supported by Mr. McAdam Eccles, who thought altruism could be carried a little too far. Sir Henry Brackenbury pointed out that only the Licensing Bodies had any power in this matter, and all of them except the Scottish Colleges were agreed on this resolution. The B.M.A. had no power over them, but could, of course, express an opinion. The Chairman of Council was anxious that this motion should not suggest that the Association had been idle in this matter; it had done everything in its power. —Mr. Bishop Harman said that the Association had never gone straight to the Scottish Colleges and told them the opinion of the profession. Torquay agreed to put its resolution in the form of an instruction to take this direct action, and thus carried it.

Scotland

Dr. J. B. Miller presented the Annual Report under Scotland. Among other activities the Committee had, he said, given evidence on the training of nurses. A great change had taken place in nurses' training since 1929 and it was possible for a girl to go through her full training without ever nursing pneumonia, which was now treated in municipal hospitals. She could only get a full training by moving from hospital to hospital for about eight years. The Association had recommended a period of five years and three months, the first year to be an academic one which could bridge the gap between school-leaving certificate (recommended as the standard of entry) and hospital work. A pension scheme had been urged. Free choice of consultant had now been ensured for Scottish teachers.

Dr. E. R. C. Walker proposed for Aberdeen, and the Chairman of Council accepted, that :—

> "In view of the new ideas on the administration of Health Services which developed in the course of the preparation and giving of Evidence on behalf of the Association by the Scottish Committee before the Departmental Committee on Health Services, it be remitted to Council to reconsider and, if necessary, revise that part of the Association's General Medical Service Scheme for the Nation which deals with the administration of Medical Services."

The units, he said, rarely corresponded with any local authority, and some coördinating mechanism was needed. He deprecated the establishment of yet another committee to deal with medical services and did not think a local authority was properly equipped for this function. "For forms of government let fools contest; whate'er is best administered is best," he concluded.—Sir Henry Brackenbury thought the proposition was a possible one for Scotland but impossible for England and Wales.—Dr. R. A. Picken did not agree, but the Chairman ruled that it was being considered for Scotland only.—Dr. G. Dunlop (Glasgow) said the position of Scottish negotiators would be made very difficult if the motion were not passed.

Medical Education

Sir Henry Brackenbury proposed the approval of the report of the Medical Education Committee, including its special curriculum recommendations.[1] The committee observed with approval several recommendations made to the General Medical Council by its own committee, but noted that a few were not in accordance with the Association's views. Every observation made by the B.M.A. would be taken into serious consideration by the G.M.C. in November. Dr. R. K. Robertson (Sheffield) did not agree that the minimum age for registration should be 18, as the course was already long and some people were older at 16 than others at 20. The Chairman said he thought this report was one of the finest reports on education that had ever been produced, and it was very largely due to Sir Henry Brackenbury. The motion of approval of the report was carried with acclamation.

Dr. Mona MacNaughton proposed for Newcastle :

> "That in arranging the curriculum for students, steps should be taken to ensure that they have a course of instruction with an approved general practitioner after their qualifying examination, but before they are entitled to register."

She thought that this would greatly increase the efficiency of the practitioner. The art of medicine was found in no text-book and was invariably learned by the young doctor from his elders and betters. Minor ailments and treatments, early signs of disease, the working of the National Health Insurance Acts and the business side of practice could only be learned this way. Moreover, the training would be invaluable for those who were not going into general practice, and would lead to better coöperation between the different branches of the profession afterwards. It could never be in the public interest that a doctor should take on a practice single-handed the day after qualification. Loud and prolonged applause greeted her speech and Sir Henry Brackenbury agreed with every word of it except her hope that the motion would be passed. The recommendation could not be carried out at the present time, he said. The Committee thought the period of responsibility should be within the five years' curriculum; nor was it convinced that service as an assistant was the sole means of acquiring responsibility under supervision. At the moment the curriculum should not be prolonged for this purpose. Newcastle refused to withdraw the motion.—The Chairman of Council expressed agreement with both parties and advised the Representative Body to move to the next business, which it did.

---

MEDICINE AND THE LAW

With all Due Respect

It is our national habit proudly and gladly to honour our judges. Especially do we hold in regard the Lord Chief Justice of England. His judicial reputation laymen must leave to the Court of Appeal. Even laymen, however, can appreciate his sincerity of purpose and his happy gift of eloquent exposition. The medical profession in particular can recall several judgments which have revealed his intimate understanding of the responsibilities of surgeons and physicians. We hope then that we may attribute to some mere hot-weather aberration a brief incident reported from the Central Criminal Court last week. A man named Quarry was being tried for the wilful murder of his wife. The defence was epilepsy. A specialist in mental disease, called by the defending counsel, stated that he had examined Quarry in prison and that in his opinion Quarry suffered from epilepsy; during an epileptic attack, he explained, the patient would not know what he was doing or whether it was right or wrong. Then followed this question from the bench:—

The Lord Chief Justice: "I want you to answer this 'Aye' or 'Nay.' Did you not go to see the prisoner on July 6th for the purpose, if possible, of swearing afterwards that he was epileptic?"

The Witness: "Certainly not."

Members of the public, we find, confirm the view that Lord Hewart's question conveyed the suggestion that a medical witness was ready, for payment; to swear what was wanted rather than what was true. If that is the innuendo, we profoundly regret an inurbanity which must render uncomfortable the future appearances of medical witnesses in Lord Hewart's court. The question was one which we should hope that few judges would permit to be put by counsel to a professional witness. When it is put directly from the bench, the apparent discourtesy affronts the whole profession.

There are legal entomologists whose humour it is to collect and classify the bees that sometimes buzz within the judges' bonnets. No evidence of judicial apiculture will ever make us reverence our judges one whit the less. The murmurous hum of little wings is happy proof that the almost supernatural beings who wear the ermine are of the same human clay as ourselves. We still look to them to be the guardians of our ancient liberties, to sound from the church tower the tocsin warning us against the encroachments of the bureaucracy, no matter what bats are in the belfry. As the recent case at the Old Bailey reminds us, Lord Hewart has not infrequently attacked the medical attitude towards criminal responsibility. Of this we have no complaint whatever. Let it be granted that the law is crystal clear and that the foolishness of doctors merely befogs it. The doctor is brought into court to provide the material of facts and opinions out of which lawyers on one side or the other will spin their legal arguments. Undoubtedly there are two aspects of the problem of crime and insanity. Undoubtedly, when the issue is the nature and degree of the patient's malady, the origin, development, and treatment of his abnormality, then the medical view is entitled to consideration. When the issue is the accused man's responsibility under the law, then Parliament, the judges, and the Home Office must have the last word. On the existence, the symptoms, and the physical effects of epilepsy doctors are entitled to be heard. The difficulty of diagnosis, the risk that dangerous criminals may go unpunished through the success of a too facile defence—these are matters on which any judge may justifiably insist. It will hardly be denied that the law prefers to stand still while the science of medicine aspires to gradual progress. In 1922 a Lord Chancellor set up a committee to consider what changes, if any, were desirable in the existing law, practice, and procedure of criminal trials where the defence of insanity is raised. A distinguished judge, Lord Atkin, presided over the committee; its membership admirably blended the wisdom and experience of the bench, the Home Office, and the experts who are concerned to prosecute in criminal cases. The committee found that changes were desirable. Legislation, it observed, might be necessary. No such legislation has since been passed; the desirable changes are not yet made. While the law thus stands, we cheerfully admit that it is the exclusive function of the judges to expound it. It may well be their duty to remind us that in a court of law it is the legal, not the medical, view which must prevail. But it will be a matter of profound disappointment and surprise if this judicial task cannot be performed without discourtesy. May we beg for some token that the offensive question will not recur? If there were not a prejudice against judicial journalism, we could respectfully have offered Lord Hewart the hospitality of our columns for the purpose. As things are, we look anxiously for some reassurance that medical witnesses can continue to give evidence in his court without apprehension.

Alleged Food Poisoning

In Cattermole *v.* Marks and Spencer, Ltd., the plaintiff failed last week in a claim for damages for alleged breach of implied warranty that a tin of peas bought at the defendants' shop was fit for human consumption. Her case was that she opened the tin, washed and cooked the peas for the Sunday luncheon of her husband and herself. The other food consisted of chicken, potatoes, fresh greens, stewed fresh plums and cream. The husband did not eat the peas and suffered no ill-effects; she herself ate freely of them and after a few hours felt very ill. Next morning a rash developed. On the Wednesday her doctor diagnosed food poisoning: for some days she was acutely ill, her face was swollen and the rash spread all over her body. After six months her doctor was still attending her. The defendants suggested that she suffered from acute dermatitis, possibly caused by some external agent such as a hairwash; but the plaintiff and her hairdresser repudiated this explanation. The defendants proved that they bought all their tinned peas from a Stratford-on-Avon firm, their purchases exceeding two million tins and this being the first complaint. Analysis of similar tins of peas showed no living bacilli or spores. The modern methods of cleaning and sterilising fruit in the canning industry were explained. It was contended that, if anything went wrong with the peas, the harmful results could not be limited to one tin, since the contents of 600 tins were prepared at the same time; the only risk would be from a "blown" tin where the fault would be in the metal, not in the fruit, and where the peas would have a frothy look and the taste of them would at once show that something was amiss.

Mr. Justice Lewis was satisfied that Mrs. Cattermole had suffered as alleged, but he said it did not follow that her claim could succeed. A rash of the skin could result from eating food perfectly fit for human consumption, through some idiosyncrasy of the person eating it. The judge was impressed also by the absence of vomiting and diarrhœa. He could not disregard the evidence of the precautions taken by the canning firm at Stratford-on-Avon. He was satisfied that their methods were scientific and up to date and that the possibility of contamination was extremely remote. He found that the plaintiff had failed to make out her claim. His judicial tribute to the manufacturers' methods will be valued by the British canning industry, which has been fostered and developed by the Ministry of Agriculture. Counsel for the defendants was at some pains to combat the impression that tinned food was more likely to be harmful than fresh food. Nowadays, he claimed, scientific preparation and sterilisation caused tinned food to be less likely to contain poison than fresh food.

INTERNATIONAL NEUROLOGICAL CONGRESS

THE FIRST DAY'S PROCEEDINGS

NEUROLOGISTS from forty-two countries met at the Second International Neurological Congress which was held in London this week. The congress was opened by the president, Dr. GORDON HOLMES, F.R.S., who laid stress upon the necessity for international coöperation as the basis of progress in truth and knowledge.

The Epilepsies

The first day was devoted to a discussion of the epilepsies.

Prof. JEAN ABADIE (Bordeaux) remarked upon the striking change in the conception of the nature of epilepsy which had occurred during the last fifty years. Epilepsy was no longer regarded as a true disease, but merely as an anatomo-clinical syndrome. He considered that it was neither constitutional nor innate, but personal and acquired. It was not a neurosis without an organic substratum but a syndrome always the result of cerebral lesions, however variable their nature. The commonest causes were lesions of the brain produced by obstetrical injuries, cranio-cerebral injuries occurring in childhood and the toxi-infective states of infancy, among which congenital syphilis was specially mentioned. It followed that there was a real ætiological link between epilepsy and infantile convulsions.

Dr. WILLIAM G. LENNOX (Boston) described the results of some striking investigations which had been carried out in his own laboratory. He considered only the rôle of the cerebral circulation and of oxygen metabolism in the production of epileptic convulsions. The flow of the blood through the brain had been recorded in 10 patients. There was no decrease in the blood flow before the convulsion and no evidence in support of the time-honoured theory that an epileptic attack was the result of generalised cerebral arterial spasm. Nor was there any evidence that anoxæmia was a cause, though in 13 patients who suffered from petit mal an attack could be induced by anoxæmia, and it had been shown that a raised oxygen tension in the blood of epileptics diminished the ease with which convulsions could be produced by over-breathing. Dr. Lennox said that hitherto there had been no method of discovering what was happening to the cerebral neurones themselves during an epileptic fit. This gap in our knowledge had now been filled by electro-encephalography, a method of recording changes of electrical potential within the brain. Records had been made from the brains of 31 patients, who all showed abnormal waves beginning before the attack and increasing in amplitude during the attack. No waves were visible during the phase of post-epileptic stupor. Petit mal seizures were invariably preceded or accompanied by a burst of electrical potentials of about ten times the voltage and about one-fifth the frequency of the patient's usual potentials. The form of the large waves was individual for each patient. Furthermore, the electro-encephalograms of patients recorded during phases of freedom from attacks showed similar but smaller disturbances of rhythm suggestive of larval or sub-threshold seizures. The interpretation of these phenomena was uncertain, but it appeared that during an epileptic attack an abnormal synchronisation of nerve impulses occurred and there was an integration in time, so that the harmony of the symphony orchestra was reduced to a single note.

Prof. E. A. SPIEGEL (Philadelphia) said that the fundamental mechanism in the pathogenesis of convulsions must be sought in alterations in the excitable nervous elements themselves. Excitation had been attributed to changes of ion concentration on semi-permeable cell membranes. As a result of the semipermeability polarisation phenomena occurred that could be used to measure changes in permeability. It had been found that states productive of convulsions—such as asphyxia, anæmia and increased intracranial pressure—caused a fall in conductivity of the brain, but the opposite effect was produced by narcotics.

Dr. F. FRISCH (Vienna) discussed the rôle of disordered metabolism in the production of epileptic attacks. He emphasised that metabolism played essentially a dynamic part and said that the typical feature of the metabolism of the epileptic was its lability. Changes had been described in many metabolic functions. There was often a preparoxysmal depression of nitrogen excretion in the urine. The metabolism of water and of salt had an important bearing upon changes in colloidal structure. The acid-base ratio had also been investigated, and it had been shown that alkalosis, in the sense of deviation of the actual reaction of the blood towards the alkaline side, was an important ætiological factor in precipitating the epileptic attack. There was as a rule a preparoxysmal diminution in the alkali reserve. A problem of current interest was the question whether sugar metabolism had any bearing upon the ætiology of epilepsy. The importance of metabolic changes lay in the fact that the excitability of the ganglion cells of the nervous system was a function of the chemical organisation of the cell.

Dr. K. ORZECHOWSKI (Warsaw) discussed the part played by the vegetative nervous system in the pathogenesis of epilepsy. He said that in genuine epilepsy the final and immediate cause of the attack was vascular spasm, the localisation of which determined whether the attack was epileptic, narcoleptic, or took some other form. None of the changes which might precede the attack, whether hormonal or vegetative, chemical or hæmatological, were peculiar to epilepsy, and hence they could only act as precipitating factors. In epilepsy proper the spasm occurred in the cortical vessels; in narcolepsy in those of the base of the brain; in pyknolepsy in the vessels of the cerebellum. The anatomical substratum of epilepsy was the complex pia-arachnoid—vasomotor nerves—vessel.

Prof. M. MINKOWSKI (Zurich) reviewed the pathological anatomy of epilepsy. He said that in patients who had died of status epilepticus recent changes were found in the tissues of the nervous system. The vessels of the brain showed congestion. The ganglion cells of the parenchyma of the nervous system exhibited acute degenerative changes in the form of chromatolysis and swelling. Changes were also found in the neuroglia and in the choroid plexuses and the ependyma of the ventricles. In epileptics in whom the disease was of long standing proliferation and thickening of the walls of the cerebral vessels was found. In the nervous parenchyma there was the well-known sclerosis of the cornu ammonis, and elsewhere, especially in the cerebral cortex, were alterations of a degenerative, atrophic or sclerotic character. Chronic changes had also been described in the glia and in the choroid plexuses. In the meninges a serofibrinous or cystic arachnoiditis had been noted. Persistence of the thymus and various chronic changes in the endocrine organs had been described.

Dr. A. Ulrich (Zurich) discussed the medical treatment of epilepsy. The administration of bromide had been controlled by an accurate estimation of the bromide content of the blood. It had been found possible to correlate the bromide level with the degree of narcosis produced in the patient. The antagonism between bromide and chloride had been investigated and it had been found that when twice or three times as much sodium chloride as bromide was administered symptoms of bromide intoxication did not appear. The bromide in the blood must be maintained at a level which depended upon the severity of the epilepsy.

Prof. Wilder Penfield (Montreal) spoke on the surgical therapy of the epilepsies. He pointed out that a focal lesion of the brain was present even in cases of so-called idiopathic epilepsy more often than was generally supposed. When the history, the presence of abnormal physical signs in the nervous system or the pattern of the attacks suggested the possibility of a focal lesion an encephalogram should be carried out and an attack observed. When the brain had been exposed at operation the cortex should be investigated by electrical stimulation. The lesions which lent themselves to surgical treatment were a scar uniting the meninges to the brain and areas of focal cerebral atrophy and cicatrix. The excision must be made through normal brain tissue and should, if possible, reach the ventricle. Of 22 patients treated by radical excision of a meningo-cerebral cicatrix 10 had remained free from attacks, and 7 were markedly improved. In another 22 cases radical excision of areas of focal atrophy and focal cerebral cicatrix had been performed, and of these patients 9 were free from attacks and 7 were improved.

Dr. M. Sgalitzer (Vienna) described favourable results achieved in epilepsy by X ray irradiation and the technique he employed.—Dr. L. J. J. Muskens (Amsterdam) referred to the difficulties of treating epileptic patients at general hospitals and the advantages of special institutions for this purpose.—Dr. H. Urban (Vienna) gave an account of the therapeutic effects of the lumbar insufflation of air and the intracarotid injection of thorotrast.—Papers were also read by Dr. A. E. Kornmüller (Berlin), Dr. A. Schüller (Vienna), and Prof. G. Stiefler (Linz), and Prof. Otto Marburg (Vienna) summarised the discussion.

Battersea General Hospital.—Six wards of this hospital, which had been closed for lack of funds, were reopened on July 29th through the generosity of Mr. S. E. Parkes, chairman of the board of governors. Mr. Parkes has given the hospital £10,000.

LIFE ASSURANCE MEDICINE

THE INTERNATIONAL CONGRESS

Representatives from all over the world were attracted to the triennial Congress of Life Assurance Medicine held last week in London at the offices of the Prudential Assurance Company. Besides the medical meetings the programme, which extended from July 23rd to 27th, included a reception by the Minister of Health at Lancaster House, a banquet at the Dorchester Hotel, and a reception by Sir Edgar Horne, chairman of the Prudential Assurance Company.

Methods of Estimating Risks

The first of the medical meetings was given to a discussion on methods of estimating risks. Reviewing the main points to be considered in the general estimate of risks, Dr. Josef Sturm (Munich) laid stress on the importance of the "moral standing" of the applicant, the relationship of his financial position to the sum proposed, and the possibility of any speculative element about the assurance. The assessment of substandard risks involves in the first place the medical estimate of the degree of impairment present, and for this purpose the experience gained from statistical work has been of great value in enabling insurance protection to be extended more and more to lives which have hitherto been uninsurable. Dr. Sturm proceeded to discuss the three methods most commonly used in the technique of extra rating:

(1) the imposition of an extra premium during the whole or only a part of the term of the policy;

(2) addition to the age of the proposer; and

(3) limitation of capital payments—this limitation continuing throughout the term of insurance or being wiped off during the earlier years of the policy. An example of this last form of limitation is the "one-fifth graduation policy" which implies that when death occurs in the first policy-year the company pays only one-fifth of the assured sum, in the second year two-fifths, and so on, with the result that after five years the whole sum becomes due in the event of death. This system has the advantage of not involving an extra premium.

Dr. Chester T. Brown (Newark, N.J.), began by describing the fundamental work of Dr. O. H. Rogers and Mr. A. Hunter whose "numerical system" for estimating risks resulted about forty years ago in the statistical approach to life assurance problems gradually supplanting the clinical. The extent of the dependable information on which modern practice rests is illustrated by the fact that the Medical Impairment Study published experiences in 1931 concerning 2,100,000 lives, one-third of which were classed as substandard. Dr. Brown proceeded to describe in more detail the working of the numerical (or statistical) method; debit and credit marks are given to the proposer under a variety of headings, such as build, family history, occupation, and habits.

Prognosis of Hypertension

The second meeting opened with a communication from Dr. Etienne May and Dr. Jean Ollivier (Paris), who pointed out that even moderate increases in blood pressure had long been held to involve a considerable increase in the risk to assurance companies; whereas private statistics gave an impression of much less gravity. The available statistics were open to two criticisms. First, the majority of them are based on systolic pressures only, since until quite recent times few observers have paid attention to the diastolic pressure. Secondly, being mass statistics they combine in the same group all individuals with the same systolic pressure whatever the cause of the hypertension and whatever its clinical type. For accurate assessment separate statistics, graded according to the clinical type of hypertension, are essential. Three main types may be differentiated: (1) Systolo-diastolic or complete hypertension; (2) the hypertension of arterio-sclerosis with systolic predominance; and (3) hypertension with systolic predominance associated with neuro-vegetative instability. In complete hypertension the rise in systolic pressure is secondary to the rise in the diastolic, and there should be a fairly constant relation between the two. Extra risk is indicated by convergence (usually due to weakening of the heart) or by divergence (indicating arterio-sclerosis). As the rate of development of hypertension is important it is advisable to defer acceptance for several months so that this may be estimated in a second examination. In arterio-sclerotic cases, attention must be paid to the condition of the kidneys and myocardium and local forms of arteritis must be looked for. The hypertension of neuro-vegetative instability may exist by itself but is commonly associated with hyperthyroidism and tachycardial neurosis. It is found in young neurotic subjects and in women at the menopause. Even when occurring with a fairly high maximum it is essentially a variable and benign hypertension. The prognosis depends more on the associated neuro-vegetative instability than on the hypertension, and in practice a margin of 10 mm. may be allowed for the systolic and 5 mm. for the diastolic pressure without extra premium. A small extra premium is required for higher readings because of the unstable nature of the condition and the theoretical possibility of its developing into a complete hypertension. In the obese, when hypertension yields readily to diet, a moderate extra is sufficient; but when it cannot be reduced the strain on the heart is such that heavy loading is necessary.

Prof. WINTERNITZ (Trieste) also emphasised the importance of the classification of hypertension according to its cause. All applicants with hypertension of renal origin should be excluded and the selection subsequently checked by a study of the cause of death; a high frequency of uræmic deaths indicating faulty selection of material. He also called attention to the importance of examining the optic discs for evidence of albuminuric retinitis, and of the electrocardiogram, without which early lesions of the cardiac muscle cannot be detected. Although the diastolic pressure might be useful in prognosis, Prof. Winternitz had so far found its value uncertain because of the difficulty of obtaining exact readings.

In the discussion which followed, several speakers agreed in regarding uncomplicated and moderate hypertension as relatively benign. Dr. TOMASSON (Iceland) found the mortality in complete hypertension six to eight times as great as when the systolic pressure only is affected.

Acceptance of Diabetics

SIR WALTER LANGDON-BROWN, president of the Congress, opened the morning session on July 25th with a paper on The Acceptance of Glycosurics. There is no doubt of the increased prevalence of diabetes, he said, and the increase is of particular interest to assurance companies on account of its tendency to affect well-off people who insure their lives heavily. The effect of insulin has been to produce a fall in the death-rate in the young diabetic which is compensated by an increased mortality in the elderly. In life assurance work, when sugar is found in the urine, the onus of proving that the glycosuria is benign rather than diabetic rests on the proposer, and the necessary blood-sugar estimations, being in any case to his advantage, should be carried out at his expense. Sir Walter had hoped that blood-sugar curves would solve all diagnostic difficulties but, as Dr. Batty Shaw had recently pointed out, biochemists are now prepared to admit that anxiety, excitement, and diet may so far influence a curve as to make the diagnosis difficult. The small mumber of intermittent glycosurics who subsequently develop diabetes justifies their acceptance, but proved diabetics remain uninsurable, since their lives depend on their maintaining proper treatment, and even when controlled they are abnormally liable to sepsis, tuberculosis, and arterio-sclerosis.

A joint paper by Prof. HIJMANS VAN DEN BERGH and Prof. C. DE LANGEN was read by the latter. They pointed out that although life assurance companies were commercial institutions their fundamental principle was humanitarian, and in actual fact substandard proposers were more in need of insurance than the perfectly sound who were likely to exceed the average duration of life. They suggested that it may be advisable to accept, suitably loaded, proposers with uncomplicated diabetes provided that personal and social conditions are favourable. Renal glycosurics should be accepted at ordinary rates.

In the subsequent discussion, Dr. CHESTER BROWN described a rapid method of blood-sugar examination. Dr. BATTY SHAW called attention to the fact that assurance companies lost heavily from diabetes in candidates who had no glycosuria on acceptance, whereas the deaths from diabetes amongst those loaded for glycosuria were few.

Peptic Ulcer

In a paper on gastro-duodenal ulceration and life assurance, Prof. ROMANELLI (Rome) remarked that although the disease was increasing, we were still without statistics reliable enough for a proper assesment of its mortality. The diagnosis may easily be made difficult if the proposer conceals his symptoms, since definite objective signs are often absent. Radiological examination is not always easy to obtain, but Prof. Romanelli suggested that large towns should be equipped for this purpose. The prognosis depends on the general condition of the proposer and the time elapsed since his last symtoms; if pain is present the risk should be deferred; after six months it may be accepted with a heavy load. Better rates may be given after five years of good health, but a proposer with a history of gastro-duodenal ulceration should never be accepted at normal rates.

Dr. FAROY and Dr. CARRIÉ (Paris), in a joint communication, also lamented the incompleteness and misleading nature of statistics concerning gastro-duodenal ulceration. They believe the total death-rate in these cases to be about 23 per cent. although it seems to be considerably lower in cases treated medically for a long period (Moutier 5·17 per cent). Surgical treatment, in skilled hands, gives excellent results (48–65 per cent. cures), but late complications, such as the appearance of jejunal ulceration, are common. Being a serious and recurrent disease, gastro-duodenal ulceration always entails an increased risk and a short-term contract. It is to the advantage of companies to require that such policy-holders should present themselves for periodic examinations, and for this purpose it is essential for them to possess clinical, radiological, and laboratory facilities.

Dr. Arthur Westerman gave it as his opinion that after five years of good health a candidate could be accepted at normal rates. Dr. Chester Brown considered the danger of relapse to be greater after surgical than after adequate medical treatment.

Periodic Examinations and Medical Care

Dr. S. B. Scholz, Jnr. (Philadelphia), opening the session on health service and life assurance on the 26th, began by describing the beginnings and the growth of the system of periodic examinations of insured persons inaugurated by assurance companies. Following a suggestion made in 1861 by Dr. Horace Dobell of London, the movement began with the Provident Life Assurance Society of New York which established a health conservation bureau in 1909; this was followed in 1913 by the foundation of the Life Extension Institute which now carries out the health service of a large group of companies. At present more than a third of the American companies provide some form of free health service. Friendly societies in America provide not only health service and life assurance, but for many years have had a sanatorium for the treatment of those of their members who contract tuberculosis.

Dr. Otto Neustätter (Berlin) spoke of the spread of health service from the United States to more than twenty other countries in the last twenty-five years. Health service might be divided into two types: prophylactic, which included education campaigns by means of leaflets, lectures, and films; and therapeutic, which included visits by nurses and also financial assistance in cases of illness. He estimated, from figures obtained in America, Germany, and Japan, that periodic examinations would lead to prolongation of life in about twenty five per cent. of cases.

Other Problems of Assurance

The final afternoon session was occupied by a series of short communications.

Prof. Bergstrand (Stockholm) read a paper on the possibility of diminishing premiums by estimating risks. He began by saying that assurance companies were to be looked on less as a trade than as a social service. There was an admirable tendency in modern times to widen the portals of entry. Whereas in 1870 only 60 per cent. of proposers were accepted at ordinary rates this figure had risen to 95 per cent. in 1933; 3 per cent. showed an expected mortality up to seventy per cent. and were accepted at an increased premium, and only 2 per cent. were rejected.

Dr. L. Wagner (Berlin) spoke of the advantages of an X ray examination in assurance work; many serious diseases, which provided no abnormal physical signs, could easily be detected by this means.

Dr. H. J. Coert (The Hague) gave the results of a statistical inquiry he had made regarding the mortality of insured diabetics. Considering patients with a small amount of sugar in the urine and no complications, he found those of average weight showed a mortality of only 94 (normal 80), whereas the overweight members of the same group had a mortality of 252.

Dr. Augusto Bunge (Buenos Aires) spoke on the joint organisation of medical examiners, which has proved a useful system in the Argentine Republic where vast thinly populated areas have to be dealt with. Fraudulent attempts are best met by coöperation between assurance companies and the appointment of a relatively small number of reliable examiners. The lengths to which criminal ingenuity can go was well illustrated by a case in which a man dying from tuberculosis was impersonated by a healthy person accepted as a first-class life. The imposter proceeded to stage a death from pneumonia, with the assistance of a doctor, who was also the assurance company's examiner.

In closing the congress the president spoke of the high place which assurance now occupied in scientific medicine. He thought the main problems for the future were concerned with the extension of the benefits of assurance still further to substandard lives. Among other drawbacks, total rejection had a bad psychological effect.

INFECTIOUS DISEASE

IN ENGLAND AND WALES DURING THE WEEK ENDED JULY 20TH, 1935

Notifications.—The following cases of infectious disease were notified during the week: Small-pox, 0; scarlet fever, 1549; diphtheria, 956; enteric fever, 44; acute pneumonia (primary or influenzal), 472; puerperal fever, 36; puerperal pyrexia, 116; cerebro-spinal fever, 9; acute poliomyelitis, 7; acute polio-encephalitis, 1; encephalitis lethargica, 5; continued fever, 1 (Birmingham); dysentery, 19; ophthalmia neonatorum, 96. No case of cholera, plague or typhus fever was notified during the week.

The number of cases in the Infectious Hospitals of the London County Council, on July 26th was 2576, which included: Scarlet fever, 729, diphtheria 965, ; measles, 43; whooping-cough, 399; puerperal fever, 20 mothers (plus 5 babies); encephalitis lethargica, 269; poliomyelitis, 2. At St. Margaret's Hospital there were 19 babies (plus 9 mothers) with ophthalmia neonatorum.

Deaths.—In 121 great towns, including London, there was no death from small-pox, 1 (0) enteric fever, 9 (0) from measles, 3 (0) from scarlet fever, 17 (1) from whooping-cough, 15 (4) from diphtheria, 45 (8) from diarrhœa and enteritis under two years, and 19 (2) from influenza. The figures in parentheses are those for London itself.

No general increase is reported in the deaths from diarrhœa and enteritis; Liverpool reported 9, Birmingham 4, no other large town more than 2. Of the fatal cases of measles 4 occurred at Liverpool. Of the 16 deaths from whooping cough outside London 4 occurred at West Ham, 2 each at Birkenhead, Leeds, and Liverpool.

The number of stillbirths notified during the week was 290 (corresponding to a rate of 42 per 1000 total births), including 44 in London.

Grantham Hospital.—The six private wards built as part of the extensions to this hospital are now complete. The charge is £5 5s. a week, and subscribers of £2 2s. a year, whose income exceeds £8 a week, are entitled to 15 per cent. reduction, and those whose income does not exceed £8, to a reduction of 25 per cent. Pay-beds are also available in the children's wards.

Gifts to Hospitals.—Mr. E. W. Meyerstein has given an additional 25 acres of land to secure the skyline of the future site at Banstead Wood, Surrey, of the Princess Elizabeth of York Hospital for Children. He has already given £10,000 to the institution. Mr. Meyerstein has also given £12,000 to the London Hospital to provide a swimming bath for the nurses. His further gifts to the Middlesex Hospital medical school were announced at the centenary celebrations reported elsewhere.

THE MEDICAL DIRECTORY

UNCOMMUNICATED ADDRESSES

THE Editor of the "Medical Directory," 40, Gloucester-place, Portman-square, London, W.1, desires to notify members of the medical profession that certain of their number, whose names appear below, have not communicated to him their present address. He asks that the persons in question, or their friends, will kindly give him the information at once, and in any case not later than Sept. 2nd. Otherwise the words (*address uncommunicated*) will appear in lieu of an address in the forthcoming 1936 issue. The date of registration is shown in parenthesis.

PANEL AND CONTRACT PRACTICE

Baths

The insurance committee for a county borough on the outskirts of London has decided to make representations to the town council, urging that in connexion with the extension and development of a civic centre for the borough provision should be made for the establishment of remedial, medical and Turkish baths. The committee were of the opinion that such facilities would prove a valuable addition to, and should be made available as part of, the existing local health services. The committee had previously approached the town council as to the desirability of making provision locally for the physical treatment of those suffering from rheumatic diseases, and the proposed development of the civic centre afforded an opportunity of considering the provision of such special baths. The local panel committee are being asked to give the matter their consideration and support.

Checks on Extravagant Prescribing

Remarks by a non-medical member of the London insurance committee upon the vexed question of prescribing have received widespread notice. This member alleged that insurance doctors are becoming intimidated and annoyed because in certain cases the Minister of Health sends regional medical officers to investigate their prescribing. The facts reported to the committee are that each year about 290 doctors whose prescribing averages are markedly above normal are selected and information as to special features of their prescribing, with other details, is submitted to the Minister. From these the Minister selects about one half, whose prescribing appears most likely to warrant investigation, and obtains detailed information from the committee. In about one-third of these cases the details given are sufficient to remove any presumption of extravagance. In the remainder (say about 100 cases), there has been prima-facie evidence that in some direction the cost of the practitioner's prescribing was in excess of what was reasonable, having regard to what on average was found adequate by other doctors in the county, and it has been considered desirable to seek an explanation. In such cases a visit is paid to the doctor by a member of the regional medical staff with a view to discussing those features of his prescribing which suggest that economy could be secured without sacrifice of efficiency. It is only in cases where, in the Minister's opinion, the evidence discloses reckless and serious extravagance that the case is finally referred to the panel committee. That committee, consisting as it does entirely of doctors, and almost entirely of insurance doctors, can presumably be trusted to ensure that nothing is done which would hinder or prevent a doctor from prescribing all drugs, however costly, which are reasonably necessary for the adequate treatment of his patients. But there are sometimes prescriptions which at first sight need explanation, for instance, "two ounces of Croton Oil. One drop to be taken on sugar when required." That would have sufficed an army corps.

Representations under Article 41

ARTICLE 41 of the Medical Benefit Regulations covers the procedure of the Ministry in cases when it is proposed to withhold from an insurance committee such amount as the Minister thinks fit from the money payable for the purposes of medical benefit with a view to the recovery by the committee from the practitioner or chemist concerned of a like amount by deduction from his remuneration or otherwise. Before deciding to withhold any such amount, unless the facts have already been the subject of an investigation in the course of an appeal made to the Minister, the latter must afford the practitioner or chemist a reasonable opportunity of making representations, either written or oral, on the matter; and where oral representations are made the Minister may appoint persons to hear the case and to report to him thereon. The insurance committee and the panel or pharmaceutical committee, as the case may be, are entitled to be represented at, and to take such part as the tribunal may think fit in, the hearing. An advisory committee assists the Minister in the discharge of his duties under the section. It will be observed that not only the insurance committee but the panel or pharmaceutical committee has certain rights in the case of oral representations, but the position is less clear when the doctor or chemist submits written representations in the matter.

The Cheshire insurance committee recently recommended that one pound should be withheld from a chemist, and the Minister adopted the recommendation. But in the letter conveying his decision to the chemist, a copy of which was sent by the Department to the committee, the Minister referred to certain representations made in writing by the chemist, whereupon the committee requested and obtained a copy of these representations. The committee took the view that had they been aware of certain contentions of the chemist these could have been refuted, and decided that the Minister should be requested, before making final decisions, to send a copy of any such representations to the insurance committee. The reply of the department was that the Minister regretted that in view of the intention of Article 41 of the Medical Benefit Consolidated Regulations, 1928, he could not give any general undertaking to consult the committee before coming to a decision on any case, but must exercise his judgment as to the cases in which such consultation would be proper and expedient.

Notifications of Service Subcommittee's Decisions

A provincial insurance committee has decided in future to convey the findings and recommendations in medical, pharmaceutical, and joint services subcommittee cases to the parties concerned as early as possible after the meeting of the subcommittee by which such cases are investigated, but the parties are to be advised that the recommendation is subject to adoption by the insurance committee and to possible revision by the Ministry of Health. Article 33 (4) of the Regulations provides that the relevant sub-committee shall draw up a report on each case and shall present it to the insurance committee, together with a recommendation. Usually the parties to such cases are not informed of the result until the insurance committee has come to a decision.

Dispensing Hours in London

THE London local medical and panel committee have been concerned at the alleged lack of adequate arrangements for the dispensing of prescriptions after 8 p.m. and have now come to an arrangement with the secretary of the pharmaceutical committee that when a doctor complains of a lack of adequate dispensing arrangements after that hour, the doctor shall be supplied with a list of chemists in his district where it should be possible to secure the dispensing of prescriptions after the normal hours.

PUBLIC HEALTH

Nursing in L.C.C. Hospitals

THE QUESTION OF HOURS

IMPORTANT recommendations were submitted by the hospitals and medical services committee to the L.C.C. on Tuesday, and accepted, in respect of the staffing at 12 acute general hospitals, all approved by the General Nursing Council as complete training schools for nurses. The committee recall reports of the central public health committee to the Council in July 1930 and July 1931, as to the remuneration and conditions of service of female and male nursing staffs, referring to the diversity of conditions generally, including hours of duty, at the transferred hospitals and stating that it was intended to work to a 54 hours (net) week as soon as practicable both for day and night work. On Oct. 25th, 1932, the committee reported the steps taken to reduce hours of work in excess of 56 (day), 60 or 66 (night) to those hours and to bring up to 54 a week (day or night), the hours at hospitals and institutions at which fewer were worked. It is now proposed that a 54-hour week (inclusive, in the case of probationer nurses, of two hours for lectures) should be applied in these 12 hospitals for both day and night work. The working conditions for all the twelve hospitals now dealt with are to be standardised on the following basis :—

Day staff.—Span of duty, 7.15 A.M.–8.30 P.M. (probationer nurses). 7.15 A.M.–9 P.M. (staff nurses). 7.45 A.M.–9 P.M. (sisters). Time allowance for meals, 1¾ hours (excluding supper) for probationer nurses ; 2¼ hours (including supper) for staff nurses and sister. Daily "off duty" time, 2½ hours for probationers and staff nurses, 2 hours for sisters. Day off, weekly, 1 day. Wards open to medical staff 10 A.M. Wards closed at night, 8 P.M.

Night Staff.—Span of duty, 8.45 P.M.–8.30 A.M. Relief for night meals, 1 hour. Nights off a fortnight, 4.

The numbers of staff proposed are based on the adoption of these standardised conditions. On the assumption that the ward beds will be occupied by patients of acute, semi-acute, and chronic types in normal proportions, a ward unit which provides (1) day nursing staff in the proportion of approximately one unit of staff to six patients, and (2) combined day and night nursing staff in the proportion of approximately one unit of staff to four patients (both ratios being calculated on a 90 per cent. occupation of beds, and including only staff classified as nursing staff) are considered desirable. In children's wards the combined day and night ratio should be approximately 1 to 3·5. Hospitals with a number of small wards will require more generous staffing than those with large wards. Trained nurses will always be on duty in children's wards.

Special provisions concern relief staff for "days off" and "nights off," emergency staff, and sickness and holiday relief. The numbers of staff submitted include provision for four-week courses of preliminary training at the general hospital training schools.

We welcome the reduction of hours and the precision with which the span of duty, night and day, and the times off are defined. These go some way towards fulfilling Recommendations VII to XVI of THE LANCET Commission on Nursing. The provision of 1¾ hours for meals (excluding supper) implies, we may hope, that for the midday meal more than the usual half hour is to be allowed. We note with satisfaction that the daily off-time duty, though 2½ hours instead of the three hours recommended by the THE LANCET Commission, is allocated independently of the time allowed for meals. The relief of one hour for meals during a night span of duty which is 11¾ hours is hardly liberal, but on the other hand some hospitals provide no such relief and the reduction of the night duty to 54 hours in a week brings this duty down to a level lower than that worked in most hospitals.

"WOMEN ORDERLIES"

Another proposal, to employ women orderlies in these hospitals is being received with critical attention in certain quarters. The duties of these orderlies would consist chiefly of the cleaning work at present carried out by probationer nurses during their first year of training, in the proportion of one woman orderly in each ward unit with a sister in charge. The duties would generally include :

(1) Dusting, cleaning and polishing of wards, ward equipment and fittings, making up ward fires, and filling of hot-water bottles ;

(2) Cleaning sanitary annexes, and their equipment, sorting soiled linen, scrubbing bed mackintoshes ;

(3) Assisting in preparation of meals, e.g., taking round cups and plates, bread and butter trolley, tea, dinners, &c. ; clearing away crockery, cutlery utensil, &c., after patients' meals ;

(4) In chronic and convalescent hospitals and blocks, assisting with "chronic" or "convalescent" persons requiring help on account of age (e.g., elderly people and children) in feeding, washing, blanket bathing, and taking to the bath ; also assisting in the making of beds and the combing of heads ; and

(5) Assisting the senior nursing staff if required in the blanket bathing, dressing, moving, or making of the bed of a patient when the work involves the services of two persons simultaneously. Except in circumstances as indicated in (5) women orderlies will not attend ordinarily to any patient who are ill, such patients being attended to solely by members of the nursing staff.

It seems to us that it may be unwise to allow any loophole such as would be implied by the word "ordinarily" in section 5 of the duties set out above, and that in any circumstances such duties as blanket-bathing, moving, or bed-making for the patient should be confined entirely to the nursing staff in approved training schools. The cleaning of equipment in sanitary annexes (e.g., bed pans) should also in our view be among the duties of the nursing staff which should not be delegated. Even if the probationer has ample material on which to practise nursing procedures, there is a psychological disadvantage in allowing her, at an impressionable period of her training, to regard personal service to the patient as anything but work strictly within the purview of a nurse.

Nutrition Centres in London

The report of the L.C.C. school medical officer just issued[1] contains further information about the experimental nutrition centres of which five have been started in London. At first one session a week will be held at each, the children being selected by the divisional medical officer from nominations by school doctors. The primary cases to be included are those at present under observation for nutritional defect who at the periodical inspection and weighing at school have not shown improvement. Hitherto certain children found to be undernourished have been sent to voluntary general hospitals by school care committees. They were found at the hospitals (it is stated) to have no disease and were sent away with nothing done, the suggestion being made that the school service referred to hospital very trivial conditions "which wasted the time of the hospital physicians." On the other hand, the feeling is growing among the public that local educational authorities should be doing more for the ill-nourished child, especially in the very earliest stages of malnutrition. During the experimental period the selected children are to be immediately under the observation of the L.C.C. divisional medical officer, and accordingly the centres have been located as near as possible to the divisional offices where the children will be seen by a part-time assistant medical officer with special experience in pædiatrics. To each centre will be allotted an experienced nurse and an organiser with knowledge of social economics who will investigate the family budgets and dietaries and advise the parents. This organiser will keep in touch with the school care committee; he will visit the children both at home and school, and report on conditions there. In any case where a period of observation in hospital is desired this will be arranged at one or other of the L.C.C. special hospitals for children—e.g., Queen Mary's, Carshalton, or High Wood, Brentwood.

CORRESPONDENCE

GOLD TREATMENT OF RHEUMATOID ARTHRITIS

To the Editor of THE LANCET

SIR,—At the present time much investigation is being carried out to assess the value of chrysotherapy in the treatment of arthritic conditions. That we have at last in our hands a remedy as valuable as the heavy metals in the treatment of syphilis, I have no doubt whatever. That hopeless lack of enthusiasm with which one approached the rheumatoid arthritic, aware of the impotence of all one's drugs and the majority of the other therapeutic ritual, has given place to a justifiable optimism. I know that excellent results are obtained without drugs in the hospital specially equipped for physiotherapy, with facilities for prolonged and intensive treatment, but in a general hospital I think most clinicians will agree that massage, radiant heat, baths, &c., is at best a palliative, and frequently only a placebo. Three years' experience of gold treatment in a general hospital has converted my initial strong scepticism into an ardent belief in its value.

I was stimulated to write this letter by that of Drs. Slot and Deville in THE LANCET of July 20th. I, too, have discarded the intravenous route for the gold salt in preference for the intramuscular. From the standpoint of toxicity, I do not think there is as yet anything to choose between the different preparations. To ensure safety, dosage must be small. The incidence of idiosyncrasy is unfortunately rather high, much higher than in the case, for example, of arsenic. In my own experience the genuine case of idiosyncrasy is encountered about once in thirty cases; after the initial small doses one of the toxic manifestations, usually the dermatitis, will appear, often of alarming severity. Another common time for the dermatitis to appear is after about 1 g. of the salt has been given, especially when it has not been spread over a longer period than a month. To avoid this latter difficulty, I now space the dosage over a much longer period than a month, and am always guided in the timing and size of the injections by the general condition and well-being, or otherwise, of the patient. If possible, I always see the patient personally before each injection. It is thus impossible to lay down hard and fast rules with regard to dosage, but my own usual procedure is to give 0·01, 0·05, 0·1 g. at weekly intervals, allow 2 weeks to elapse, and then give, *in cases without any reaction other than increase in local joint symptoms*, 0·2 g. at fortnightly intervals for four doses. I then repeat the course in six weeks' time.

I, too, have noted relief of pain in the osteoarthritic patient, though I have not as yet treated many. I first used gold in these cases simply for the sake of "doing something" for these unfortunate patients, without anticipating benefit, but it does seem to relieve their pain, perhaps through raising their level of health. Physiotherapy should, I think, always be employed as an adjuvant to the chrysotherapy, but not until the patient has improved *in general health* and the joints become less painful. Then encourage the full discharge of the orthopædic batteries.

I am, Sir, yours faithfully,

Liverpool, July 29th. RONALD ELLIS.

BLEEDING OF TRANSFUSION DONORS

To the Editor of THE LANCET

SIR,—I am very sorry to see that Dr. Marriott and Dr. Kekwick have taken my letters so much amiss and so little in the spirit in which they were intended. If they will re-read them, I think they will see that, so far from having "found no single good word" for either of their contributions, my comments were directed against two points only, both of them subsidiary, and on neither of which they have a right to say that I have no experience. These points were as follows:—

(1) The question of "direct approach" to veins by cutting down on them; a practice that seems to me unjustifiable except in an emergency whatever method of transfusion, drip or otherwise, is employed.

(2) The question of the degree of suction to be employed when bleeding donors. While I have never used a Dunlop foot pump for this purpose, I have in the course of the last ten years used a number of different types of pump, some of them very little less powerful than that described by the writers, and, in my experience, beyond a certain point the efficiency of the pump diminished (as might be expected when withdrawing fluid from a vessel with a highly collap-

sible wall), and moreover it gave rise to the unpleasant vibration described in my letter. This is not a theory, but an actual observation. The most efficient was a rubber bulb with a wall rather thicker than a Higginson syringe, with which a pint of blood could easily be obtained in the five minutes that the writers specify. As they say, it has to be seen to be believed.

So far from wishing to criticise the actual method of drip transfusion itself, I can assure them that I shall watch its developments with the greatest interest. I am, Sir, yours faithfully,

Grosvenor-street, W., July 27th. J. W. SHACKLE.

ARTIFICIAL RESPIRATION

To the Editor of THE LANCET

SIR,—At the request of the Secretary of the Medical Research Council I have investigated a new method of artificial respiration to which attention had been drawn by the inventor, Mr. Norman Pogose. The method is as follows:—

> The patient is placed in the prone position with the face turned to one side, and the operator, standing astride, first kneels on one knee and then, passing his hands under the lower part of the body, locks the fingers together, so that the palms support the patient's abdomen in the lower part. He then rhythmically lifts up and lowers this part of the body. The lift by the action of gravity drawing any water out of the air passages, while the pressure of the hands on the abdomen forces the diaphragm up and expresses air out of the lungs. When the body is lowered air is sucked into the lungs by the elastic rebound of the thorax.

The advantages of the method are first, that no injury can be done to the ribs or internal organs, as has been done by the Schäfer method when carried out with excessive force. Secondly, the method not only forces air in and out of the lungs, but blood in and out of the right heart, and this may help to set the heart going. In the case of animals I have myself observed that some blood may even be driven through the lungs and left heart and so reach the respiratory centre by means of rhythmic compression first of the abdomen and then of the thorax. The disadvantage of the method is that it is more laborious to maintain than Schäfer's, but a succession of operators could of course keep it up; if there is only one operator available he well might alternate the Schäfer method with the Pogose method, such change being, I think, to the advantage of the patient.

With the aid of respiratory valves and a gas meter, kindly placed at my use by Sir Robert Davis, at the works of Messrs. Siebe Gorman Ltd., I have investigated on a subject the efficiency of the Pogose method in comparison with that of Schäfer and Eve.

> The last method is a very efficient and easy one to carry out given the necessary apparatus, which is supplied by that firm. The patient is suitably strapped in the prone position on a light metal frame and is rocked up and down round an axis which is supported by the two legs which carry the apparatus. The weight of the viscera in the head-downward position forces up the diaphragm and expresses air out of the lungs, while air is drawn into the lungs as the body is moved into the head-upward position.

The subject of these observations while lying prone breathed naturally 11 litres a minute. By the Schäfer method lightly applied 14 litres were artificially respired; by strong application 34 litres per minute. By the Eve method there were respired 22 by slower and 36 litres by faster rate of rocking, and by the Pogose method 17 to 28 litres per minute. The Pogose method is then amply sufficient.

Mr. Pogose sets much store on adding to the treatment by artificial respiration, and, soon after its commencement, a reflex stimulation of the nervous system. He effects this by turning over the patient and sitting him up with his back supported by the operator's legs, the hands of the operator on the front of the chest, and the thumbs placed in the supraclavicular fossa. The thumbs are used to press, five or six times in quick succession, the supraclavicular nerves against the clavicles. The patient is then laid prone again and artificial respiration continued.

Mr. Pogose claims that he has found no difficulty in teaching his method to members of the police force, and that it has been used with success in resuscitating several people. There is no doubt that his method is an efficient one; in effect it resembles Eve's rocking method, but requires no apparatus.

I am, Sir, yours faithfully,

July 30th. LEONARD HILL.

A SALARIED SERVICE OF MIDWIVES

To the Editor of THE LANCET

SIR,—In your last issue (p. 219) you suggest that organised midwives would be unlikely to support a scheme for a salaried service of midwives unless it includes the compensation of midwives not accepted for the service. The report of the Joint Council of Midwifery would not have been signed by representatives of the Midwives' Institute nor would it have been endorsed by the council of the Institute unless it had clearly recommended that all midwives in practice should have an opportunity to apply for inclusion in a salaried service and should receive reasonable compensation for giving up practice if rejected, or alternatively a pension if old or infirm.

There is no readily accessible information as to the number of independent practising midwives, their average age, length of practice, working costs, &c., which could be used to base an estimate of the cost of fair compensation and pension rates, and the Midwives' Institute has sent out 6000 questionnaires to midwives in private practice, asking for those facts. These are being returned in great numbers and Dr. Janet Lane-Claypon (Lady Forber) has most generously undertaken the considerable task of tabulating the information because she realises the value of the work done by midwives now in practice.

It is difficult to understand what the London County Council means by inefficiency. Every local supervising authority has ample powers to bring up before the Central Midwives Board midwives who break the very detailed code of Rules by which their practice is restricted.

The Midwives' Institute does not believe that the ungenerous attitude of the London County Council is likely to receive much support. It is generally recognised that midwives in this country, notwithstanding the defects in their training, the very small remuneration they receive, the unregulated competition of untrained women, their omission from national insurance schemes, the fact that they have no say in the choice of the doctor they call in when their own skill fails or is insufficient, and no direct access to hospital in emergency, can show amazingly good results and an honourable record of the care of their patients.

Changes must come, but we do not believe that it will be to the interest of mothers or the public generally to effect them at the expense of depriving of their livelihood without compensation women who, even if now superfluous, have been encouraged to come forward for training either by the often uninformed cry that there was a shortage of midwives or the eagerness with which maternity hospitals have accepted their services and their premiums.

I am, Sir, yours faithfully,

G. B. CARTER,
Organising Secretary, Midwives' Institute.
Lower Belgrave-street, S.W., July 29th.

OBITUARY

WILLIAM HOWARD JONES, M.B., B.S. Lond.

SURGEON ANÆSTHETIST, CHARING CROSS HOSPITAL

We regret to record in tragic circumstances the death of Dr. Howard Jones, a well-known anæsthetist in charge of his specialty at many London hospitals.

William Howard Jones was born in 1880 and received his medical education at Owens College, Manchester, and St. Bartholomew's Hospital, qualifying with the English double diploma in 1906 and becoming M.B., B.S. Lond. in 1913. His whole professional career was devoted to the study and practice of anæsthetics, and among the anæsthetists of London, he had achieved a notable position by his activity at their various meetings, and by the force and originality with which he was wont to state the opinions which he had formed on any subject under consideration. He had played for years a prominent part at the meetings of the section of anæsthetics of the Royal Society of Medicine, and at the time of his death held the position of secretary to the Association of Anæsthetics, which post he had occupied since the inception of the Association and for the success of which the labours of Howard Jones were in no small degree responsible. Besides the post of Hon. Surgeon Anæsthetist and Lecturer on Anæsthetics to Charing Cross Hospital, he held also those of Senior Anæsthetist to the London Temperance Hospital, and Anæsthetist to the Royal Ear Hospital and to the Royal National Orthopædic and Gordon Hospitals. Howard Jones was a keen clinical worker and was the author of several papers in which he described the methods which he employed and the opinions of the practice of anæsthetics to which his experiences had led him. One of the best of these articles is that which is to be found in the proceedings of the Royal Society of Medicine for 1924. It was entitled "The use of chloroform and the misuse of ether." Although perhaps, not so pertinent to-day when the use of gaseous anæsthetics has so greatly increased, yet Jones's justification of his paper still stands, "that the great majority of operations are still performed under the influence of ether and chloroform administered by the ordinary method of inhalation." His thesis was that, as most experts admit, there are many occasions on which chloroform is the most suitable anæsthetic to employ. He proceeded to show that "chloroform may still be of the greatest value in protecting our patients from the only too common evil effects of ether." Jones was, of course, far too experienced an anæsthetist to underrate the dangers of chloroform but, himself looking at the relative merits of ether and chloroform with an unprejudiced eye, he could twit those who are less level minded. "The word chloroform seems to provoke in some people an exhibition of almost as much fanaticism as is occasionally evidenced against that poisonous but popular liquid, alcohol." A little further on he remarks, "in both we have the unostentatious user who likes to keep a little in a convenient cupboard, or in the bottle of his gas and oxygen apparatus. Both these substances are known occasionally to damage the liver yet in each instance those are to be found, who, after all, sometimes think that the risk is worth while."

It is, however, for his work on percaine, that Howard Jones's name will be long remembered, as indeed at the present time it has become well known to anæsthetists all over the world. Particularly on the continent has this work found may admirers and imitators. His initial paper on "A new regional and spinal analgesic, with special reference to high thoracic nerve root block and a new technique" was read before the section of anæsthetics in 1930. This, as well as the still fuller paper given to the British Medical Association in the following year, contains an admirable discussion of the physics, anatomy, and physiology of the endothecal method of analgesia. Not every one agrees with the views which Howard Jones expounded, but all must admire the work on which they were based, and the forcible and lucid exposition of them which he provided. Certainly they did much to clear men's minds with regard to spinal analgesia and to disprove some commonly accepted fallacies. It was always a pleasure to listen to Howard Jones, and what he said was enhanced by the appearance of the speaker. His ruddy face, bold head, gold spectacles and plump figure completed a picture which was part Pickwick and part professor, and wholly engaging. Howard Jones left a widow and two sons to whom the deep sympathy of his many professional friends will be extended.

Mr. Macleod Yearsley writes: "The wholly unexpected death of my old friend Dr. Howard Jones leaves one of those gaps which cannot be filled when one is getting older. We first met when Howard Jones was appointed anæsthetist to the Royal Ear Hospital some thirty years ago, and we have been friends ever since that time. For years past he has given practically all my anæsthetics, and my family and I have experienced his great skill and kindness as his individual patients more than once. As an anæsthetist, Howard Jones fulfilled every requisite of character and skill. However difficult the case, whatever the complications or emergencies that might arise, he met them all with the same unruffled calm. His very presence seemed to spell safety, he never failed one, he never let one down, and I believe I am right in saying that he never had a death. He carried out a good deal of research and his knowledge of anæsthetics was very comprehensive. As an individual, Howard Jones was warm-hearted and generous-minded, but always gave the impression of being a 'self-contained' man. One had to know him to appreciate all his many good points, and he possessed a fund of quiet humour that made him excellent company."

SAMUEL ERNEST PICKEN, M.B., B.Ch. Belf., M.C.

We regret to announce the death of Dr. Ernest Picken of Bristow Park, Belfast, whose accidental death by drowning occurred on Sunday, July 14th, at the age of 45. He was a son of the late Dr. James Picken of Randalstown, and received his medical education at the University of Belfast, where he graduated as M.B., B.Ch. in 1914, his clinical training being conducted at the Victoria Hospital, where he acted for a time as medical registrar. He was appointed assistant professor of materia medica at Queen's University, Belfast. He joined the R.A.M.C., was twice mentioned in despatches, and awarded the Military Cross, retiring at the conclusion of hostilities with the rank of major. He then went into practice in Belfast, and soon became well known as a practitioner. Later he undertook the duties of medical referee under the Ministry of Labour, a post which he was holding at his untimely death. Dr. Picken had many friends, and deep sympathy is extended to his widow who was with him when the tragedy occurred, during a week-end holiday.

CORNELIUS WILLIAM SUCKLING, M.D., M.R.C.P. Lond.

THE death is announced, at his house in Edgbaston on June 30th, of Dr. Cornelius Suckling who for many years held a prominent position in the medical world at Birmingham. He was a native of Birmingham, received his education at Queen's College in that city, and graduated in medicine at the University of London in 1880 with first-class honours. He proceeded to the M.D. degree in 1882, taking also the diploma of M.R.C.P. London in the following year. He was for a time medical tutor to the students of Queen's College, and was elected physician to the Queen's Hospital and professor of medicine in the College, Birmingham, one of the institutions from which later the University of Birmingham was constructed. He held other posts in the city, being physician to the Children's Hospital, and the Birmingham Orthopædic and Spinal Hospital, and after the amalgamation of Queen's College with Mason College, he was appointed professor of medicine, holding the chair at Mason College for some five years. Dr. Suckling was from the beginning of his consulting practice interested in neurological problems. He contributed to *Brain*, the *International Medical Journal*, *The Lancet*, and the *Birmingham Medical Review* papers on various neurological subjects; he wrote on migraine and epilepsy, and held views on the significance of the movable kidney which did not meet with general acceptance. He married Miss A. M. Jerome of Sutton Coldfield who survives him, but they lost both their sons. He was 81 years old at the time of his death.

PARLIAMENTARY INTELLIGENCE

NOTES ON CURRENT TOPICS

Ventilation of the House of Lords

IN the House of Lords on July 24th the Marquess of LINLITHGOW moved: "That it be an instruction to the House of Lords Offices Committee to consider the provision for this Chamber of an up-to-date air conditioning plant." Attendance during three days' debate in that house induced, he said, in peers of the realm symptoms of that decay, that pallor, and that loss of condition from which by scientific devices the chilled banana, the frozen joint of beef, or the gassed apple were saved. Any one of the several British firms catering for this class of work was to-day easily capable of supplying apparatus which would enable that house to prosecute its labours in conditions both healthy and entirely comfortable, whatever the climatic conditions outside.—For the Office of Works the Earl of MUNSTER, Lord in Waiting, said that the present precautions were as follows: The air was drawn in at a low level from one of the courtyards, and, if the atmospheric conditions outside rendered it desirable, it was passed through water sprays. It then went through canvas screens with the object of eliminating excess moisture and impurities and a certain amount of fog. The vitiated air in the chamber was withdrawn by a fan in the roof. This installation was in advance of what was done in any except the most modern luxury buildings, cinemas, theatres, where conditions of occupation were more congested. A modern air conditioning plant, having regard to the nature of the building, would be very costly to install, and great care would have to be exercised on the grounds of noise, but its design presented no engineering difficulties.—The motion was by leave withdrawn.

Health and Safety in Mines

On July 24th, in committee of supply of the House of Commons, Captain CROOKSHANK, Secretary for Mines, said he would like to remove a misapprehension under which Mr. John was labouring last week when he spoke on the Home Office Vote (THE LANCET, July 27th, p. 225). Mr. John had said that he found no coöperation or coördination between the Mines Department and the Home Office. He would give two instances of such coöperation:

> The Departments were trying to coöperate to get the best dust respirator, which of course affected factories as well as mines; and to ascertain the efficiency of a method of laying dust after shot-firing. In the case of silicosis—one of the most important industrial diseases to-day—the Medical Research Council had a research committee dealing with causation and diagnosis. The Home Office came in to deal with compensation problems and the Mines Department came in with regard to prevention. On the prevention side there was to-day an official of the Mines Department who spent his whole time on the problem, which was a very difficult and exacting one. It was particularly baffling in South Wales, where it appeared to be on the increase, although there was no history of abnormal exposure to silica dust. On the silicosis side everything in the way of coöperation between the Departments concerned was really being done; both were represented on the research committee.

With regard to nystagmus, it was a relief to find a drop every year in the number of new cases. Between 1929 and 1933 the drop was no less than 40 per cent. He knew that there were fewer men employed, but not 40 per cent. fewer. Nystagmus had been considered to be due to bad lighting, and new lighting regulations were issued last year. Workers at the coal face must have lamps with a certain minimum performance. Those new lamps were started in use on Sept. 1st last, and a complete change over had to take place by the end of 1936. Last July the area in which mains lighting was permissible was extended, subject to certain safety precautions; it was disappointing that so little had been done. The third regulation with regard to whitewashing had brought great improvement.

With regard to accidents, the 265 casualties at the terrible disaster at Gresford had swollen the total number of fatal accidents. The total for the year was 1073, but if they excluded the Gresford disaster it was 808. The three-day accidents were 132,859. For the first six months of this year preliminary figures showed that there were 399 fatal accidents, a reduction of five compared with the same period last year. That represented a rate of 3·6 per million tons of output, the lowest rate they had had. Nevertheless, the risks and dangers of the mining industry were still something like six times those occurring in factories and workshops. In his last report the chief inspector of factories said:

> "The adult worker has become accustomed to his environment, and has—or ought to have—acquired habits of caution. The young entrant finds factory life an entirely new experience, and possesses, in addition, certain qualities of youth, such as bravado and curiosity, which render him essentially susceptible to accidents. It seems to me, therefore, that it is encumbent on us to give him an apprenticeship in safety just as in his productive work, and to see that he is not only warned, but forewarned, of the dangers inherent in all industrial life."

The factory inspector went on to suggest that the young entrant into industry should be shown the principal risks to be guarded against and supplied with copies of the safety rules. Steps should be taken to see that those who met with many accidents in their first year were put on some other job. In the autumn of 1931 propaganda was started with regard to boys, and that propaganda had spread tremendously. Last year there were 261 centres at which 10,647 boys attended. Certificates were given to those who were most successful, and 5500 of these boys received awards. This was admirable preventive work. With regard to safety equipment, most of the time of one divisional inspector was now devoted to work on that side. Summing up the work of his Department in regard to health and safety, Captain Crookshank said that research was being continued and inspection was being kept at the highest possible mark.

Mr. T. SMITH moved to reduce the Vote by £100. He said that the Labour Party thought that sufficient progress was not being made in reducing the accident-rate underground. He thought that so far as accidents at the coal face went, if there were less speed and less rush at the coal face there was a possibility that the figures might be reduced. They had to revise their opinions about explosions, the first defence against which was good ventilation. Too much shot-firing was taking place in the mines to-day. The Labour party had for many years been pressing successive Secretaries for Mines to bring in an Order making compulsory the use of gas detectors underground. There was to be a regulation from Oct. 1st, and while he believed that it was necessary and would be a step forward the Miners' Federation of Great Britain were not satisfied with the terms of the Order. They thought that there should be some consultation between the workmen and the management as to the type of detector to be used underground. He understood that every pit in the country was inspected once in 12 months, but that was not sufficient. With only 111 inspectors and more than 2000 pits it was obvious that the inspection could not be as adequate as it should be. There was a feeling among eminent mining men that the regulation governing stone-dusting ought to be revised. Instead of it being on a fifty-fifty basis the 50 per cent. should be the minimum. Stone-dusting was useless unless they used stone dust which would be effective. In the mining industry there was a good deal of poverty and far too many accidents. What the Labour Party could do to coöperate with anyone in reducing the accident-rate they would do. He recognised that the men took risks; they were compelled to do so. But all the accidents in the pits were not the men's fault. He (Mr. Smith) had seen some of the protective equipment and some of it was very good indeed, but the men in their poverty could not buy these appliances and so they were not extensively used. It would be a good investment for the owners to make provision for an extended use of this safety equipment.

Mr. ISAAC FOOT quoted two examples of the use of protective equipment in America:

> A coal company employing about 1600 men enforced the use of safety shoes and goggles commencing January, 1930, and these were the results: In 1929 there were 396 eye accidents and in 1932 there were 17. The days lost in respect of eye accidents in those years fell from 5839 to 13. Taking the accidents to the foot in the same mine in those years they fell from 184 to 5 and the days lost in respect of foot accidents fell from 1129 to 54; and the reduction was progressive. In another mine the equipment was not made compulsory but 95 per cent of the employees adopted the protective helmets. In 1929 there were 126 head injuries and on June 30th, 1932, they were down to 7, and the days lost in the same years had fallen from 693 to 26.

Colonial Health Services

On July 25th Mr. MALCOLM MACDONALD, Secretary of State for the Colonies, said the economic depression had led inevitably to the cutting down of expenditure on health services. Things were now a little better. One of the most effective ways of bringing these services into contact with large native populations was, he said, to enlist the help of natives who themselves were trained to take part in the medical and health services. There had been an expansion of some of those training institutions during the last 12 months.

Take the case of the old institution which had existed for some time in Ceylon. There the expansion had taken place by the recruitment of additional members to the staff, so that they could train at any given time an increased number of medical students. In the case of Nigeria, where they had not got an old-established institution, they were developing these services for training natives in medical work by expanding the medical course which was given there. They had now made arrangements in Nigeria which would enable natives to get full professional qualifications.

Mr. MacDonald added that more money was being spent on medical research into yellow fever, malaria, sleeping sickness, and other endemic diseases.

Dr. MCLEAN said that with regard to public health work, upon which little was heard until things began to go wrong, the medical officer of health seldom got credit for his preventive measures. Those who had been connected with the application of health measures knew the great difficulties that existed in getting that native coöperation which was so essential in matters like anti-malarial work. He remembered once remonstrating with a native about leaving stagnant pools of water which bred out mosquitoes carrying the disease. He replied quite simply, "If God wishes the fever to come here no Government regulations will keep it away.":

HOUSE OF COMMONS

MONDAY, JULY 29TH

Medical Testimony and Pension Claims

Mr. MABANE asked the Minister of Pensions whether he was aware that many soldiers of the Great War were now beginning to suffer from ailments, or were experiencing recurrences or after-effects of ailments or wounds sustained in the war, or were dying prematurely, and that in many cases it was not possible to establish an incontrovertible medical history to relate present ailments or premature death to war service; that there was a widespread sentiment throughout the country that the pledge given during the war that no soldier should fail to receive full compensation for any injury he sustained should be most generously interpreted; whether he would, therefore, consider appointing non-medical bodies of ordinary citizens, similarly constituted to common juries, to decide upon cases where there was conflict of medical testimony; and whether he would be prepared to accept the decision of such bodies as final.—Mr. R. S. HUDSON replied: I am glad to be able to assure the hon. Member that the late claims now being received, which are diminishing in number, are not determined on evidence amounting to legal proof or the absence of it, as he would appear to imagine. On the contrary, each case is decided on its merits in the light of all the evidence available, and frequently after consultation with outside specialists of eminence. I am afraid I do not consider the suggestion in the last part of the question either necessary or practicable.

Sir JOHN WALLACE: Is due weight attached to independent medical testimony which may be in conflict with the official testimony; and is my hon. friend aware that in spite of his reply very serious cases of grievance are arising all over the country on account of the lack of consideration extended to the cases referred to?

Mr. HUDSON: As the hon. member knows there is a procedure in operation by which where there is any serious difficulty the case is submitted for the advice of an eminent outside professional expert nominated by the president of the Royal College of Physicians or the president of the Royal College of Surgeons as the case might be. I think I am correct in saying that in no case has the advice of that independent expert been disregarded. In every case his advice has been taken by my Department.

Water Supply in Rural Areas

Colonel ROPNER asked the Minister of Health whether he had received any recent notification of shortage of water in rural districts; and what action he was taking.—Mr. SHAKESPEARE, Parliamentary Secretary to the Ministry of Pensions, replied: My right hon. friend has not received any recent notification of serious shortage except in a few rural areas. In all cases brought to his notice an engineering inspector visits the locality with a view to expediting the preparation and carrying out of permanent scheme. In rural areas generally good gress is being made, and so far grant has been provi- nally allocated in respect of schemes for 1360 parishes a total estimated capital cost of £3,900,000.

Poisons Board and Teaching of Chemistry

Ir. **Henderson Stewart** asked the Home Secretary e had considered the protest of St. Andrew's University inst the recent proposals submitted by the Poisons ard; and if he could give the assurance that no attempt uld be made, by vesting powers in an outside institu- n, to infringe the independence of the university as gards the teaching of chemistry.—Captain **Wallace**, nder-Secretary, Home Office, replied: My right hon. end will give the fullest consideration to the repre- tations of St. Andrew's University in conjunction th the other representations which he has received. m not in a position at the moment to make any further tement in the matter, since the statutory period for aking representations in regard to these rules only pired yesterday.

Children's Branch at Home Office

Mr. **Rhys Davies** asked the Home Secretary when it as intended to issue the next report covering the work the Children's Branch.—Captain **Wallace** replied: he staff of the Children's Branch has been so much cupied with the administration of the new Children nd Young Persons Act and other matters that it has not een found possible to review its work in another report. y right hon. friend recognises the usefulness of these ports and hopes to have one issued as soon as circum- tances permit.

Sickness in the Public Service

Mr. **Herbert Williams** asked the Secretary to the reasury if he could furnish any comparative statistics s to the respective sick absences of males and females n the public service.—Mr. **Duff Cooper**, Financial ecretary to the Treasury, replied: Statistics relating o the sick absences of some 50,000 established non- ndustrial civil servants in certain large departments, ther than the post office, indicate that the average umber of days sick leave per annum taken by men and omen during the years 1932, 1933, and 1934 were as ollows:—

Men (disabled)	11·8
,, (others)	8·6
Women	12·9

Corresponding figures for the post office, relating to bout 160,000 established persons, are:—

Men (disabled)	15·1
,, (others)	10·7
Women	12·2

Air Raid Circular to Local Authorities

Mr. **Temple Morris** asked the Home Secretary the nature of the replies received from local authorities to the recent air-raid circular; and whether he had received any refusals to take action under it.—Captain **Wallace** replied: The purpose of the circular was to convey information to local authorities, and no reply was called for. Local authorities are presumably waiting for the conferences referred to in the circular, which will be held after the holidays. No refusals to take action under the circular have been received.

WEDNESDAY, JULY 24TH

Children and Gas Mask Drill

Mr. **Morgan Jones** asked the President of the Board of Education whether any plans had been made for the training of school-children in gas-mask drill, or whether such plans were contemplated.—Mr. **Ramsbotham**, Parliamentary Secretary to the Board of Education, replied: No, Sir.

Precautions against Air Attacks

Mr. **Harcourt Johnstone** asked the Prime Minister whether instructions for compulsory "black-outs" in districts where experiments were being carried out against air attacks were issued by authority of any Government department; and, if so, by what authority such orders were given.—Mr. **Baldwin** replied: No instructions for compulsory "black-outs" have been issued or are in contemplation. These experiments, like all other air-raid precautions services, are being carried out with the voluntary coöperation of all concerned.

Mr. **Dobbie** asked the Home Secretary what plans, if any, had been made to prevent the sale of worthless, inefficient, and dangerous gas masks to the general public; if he proposed to institute financial control over such firms in order to prevent profiteering; further, if he intended to examine such products systematically in order to ensure that inefficient appliances were not sold to the general public; and if he would take steps to ensure that the durability and reliability of all gas masks, both in use and in storage, was clearly indicated on the mask when it was sold.—Captain **Wallace**, Under-Secretary, Home Office, replied: The Government are fully alive to the importance of protecting the public against the sale of respirators of inferior capabilities, and are actively investigating the most suitable means of achieving this object. Special consideration is being given to the question of inspection.

Mr. **Logan** asked the Home Secretary what quantities of bleaching powder, which could be used as a decontaminating agent against poison gas, were available; how long such reagent could be stored without deterioration; and if he proposes to recommend its use to local authorities.—Captain **Wallace** replied: Bleaching powder is an ordinary commercial product, but particulars of the available stocks cannot be stated. Its deterioration is largely a question of methods of packing and storage. Information to local authorities as to its use for decontamination purposes will be included in publications now in course of preparation.

THURSDAY, JULY 25TH

Food Value of Herrings

Mr. **Chorlton** asked the President of the Board of Education whether, as the food value of herrings was so high and the quantity available so great, he would make arrangements to supply schools in a similar manner to that which was used for milk at the present time.—Mr. **Oliver Stanley** replied: I am afraid it would prove impracticable to distribute herrings in schools in the manner suggested by my hon. friend. In view of the high food value of herrings, however, I should welcome their increased use as part of the midday meals supplied at feeding centres and school canteens.

TUESDAY, JULY 30TH

New Military Hospital at Edinburgh

Mr. **Guy** asked the Financial Secretary to the War Office what progress had been made in the negotiations between the War Office and the Edinburgh corporation for the purchase of land at Redford for a military hospital and new artillery barracks.—Mr. **Douglas Hacking** replied: No final decision has yet been reached, but it is hoped that the scheme will be completed within the next few weeks.

Mines Inspectors at Coroners' Inquests

Mr. **Tinker** asked the Secretary for Mines how many coroners' inquests were attended by His Majesty's inspectors of mines during 1934; and the highest number attended by one inspector.—Captain **Crookshank** replied: The number of coroners' inquests attended by H.M. Inspectors of Mines in 1934 was 854; in addition they attended 140 fatal accident inquiries in Scotland, where there is no coroner's inquest. The highest number attended by one inspector was 44.

Welfare Work in Mining Areas

Miss **Ward** asked the Secretary for Mines whether he would consider instituting an inquiry into the adequacy of the welfare work carried on throughout the mining areas.—Captain **Crookshank**: I would remind my hon. friend that the whole question of miners' welfare work was fully investigated by the Departmental Committee under the chairmanship of Lord Chelmsford in 1932, and there is clearly no justification for another such inquiry. I understand, however, that following upon the extension of the period of the Miners' Welfare Levy by the Mining Industry (Welfare Fund) Act of last year, the Miners' Welfare Committee is approaching the various District Committees with a view to having separate surveys made of the welfare facilities available in each district. I may add that a welfare organiser has recently been appointed for Northumberland who will commence a survey of that district shortly.

MEDICAL NEWS

University of Oxford

Dr. A. M. Cooke, has been re-elected to the May fellowship and readership for a further period of three years.

University of London

On July 17th the degree of Ph.D. was conferred on Dr. S. S. Bhatnagar, and Dr. C. E. Dolman.

At recent examinations T. F. Todd was successful in passing branch I (surgery) of the M.S. degree.

University of Manchester

Dr. James Davson has been appointed demonstrator in pathology.

Royal College of Physicians of London

At the quarterly meeting of the college on July 25th, with Lord Dawson, the president, in the chair, the following fellows were elected officers for the ensuing year:—

Censors: Sir Arthur J. Hall, Dr. Gordon M. Holmes, F.R.S., Dr. H. Letheby Tidy, and Dr. C. E. Lakin. Treasurer: Dr. Sidney P. Phillips. Registrar: Sir Raymond Crawfurd. Harveian Librarian: Dr. Arnold Chaplin. Assistant Registrar: Dr. Charles Newman. Library Committee: Dr. H. R. Spencer, Dr. J. J. Conybeare, Dr. A. E. Clark-Kennedy, and Dr. Reginald Hilton. Curators of the Museum: Dr. G. E. Beaumont, Dr. Maurice Davidson, Dr. R. A. Hickling, and Dr. Daniel Davies. Finance Committee: Dr. T. Watts Eden, Dr. C. R. Box, and Prof. F. S. Langmead.

The following were elected examiners:—

Chemistry: Mr. Herbert Lambourne and Mr. C. S. Gibson. Physics: Mr. W. H. White and Mr. Gilbert Stead. Materia Medica and Pharmacology: Dr. Philip Hamill, Dr. R. St. A. Heathcote, Dr. Clifford Hoyle, Dr. E. Gordon Holmes, and Prof. W. J. Dilling. Physiology: Prof. C. A. Lovatt Evans, F.R.S., and Prof. D. T. Harris. Anatomy: Dr. Thomas Yeates. Pathology: Dr. C. M. Wilson, Dr. C. Terence East, Prof. Geoffrey Hadfield, and Dr. P. N. Panton. Medical Anatomy and Principles and Practice of Medicine: Dr. Otto Leyton, Dr. C. M. Hinds Howell, Dr. A. G. Gibson, Dr. H. C. Cameron, Prof. A. E. Naish, Sir Stanley Woodwark, Dr. Anthony Feiling, Dr. G. E. S. Ward, Prof. W. H. Wynn, Dr. J. W. McNee, Dr. J. Forest Smith, and Dr. T. Jenner Hoskin. Midwifery and Diseases peculiar to Women: Prof. Gilbert Strachan, Mr. J. M. Wyatt, Mr. A. J. McNair, Mr. Leslie Williams, and Prof. R. P. Ranken Lyle. Public Health: Part I., Prof. M. E. Delafield, and Part II., Dr. C. T. Maitland. Tropical Medicine: Prof. J. Gordon Thomson and Lieut.-Colonel G. S. Parkinson. Ophthalmic Medicine and Surgery: Dr. F. M. R. Walshe. Psychological Medicine: Part I., Dr. R. D. Gillespie; Part II., Dr. Douglas McAlpine, and Dr. A. A. W. Petrie. Gynæcology and Obstetrics: Mr. J. P. Hedley. Laryngology and Otology: Mr. V. E. Negus. Radiology: Mr. J. H. Brinkworth and Dr. H. K. Graham-Hodgson. Anæsthetics: Dr. C. W. Morris. Child Health: Dr. Leonard G. Parsons. Murchison Scholarship (1936): Dr. H. Gardiner-Hill and Dr. C. F. Harris.

Lord Dawson was re-elected the representative of the college on the governing body of the British Post-graduate Medical School.

The president announced the award of the Baly medal to Mr. F. H. A. Marshall, Sc.D., F.R.S., as a pioneer in the experimental investigation of sexual physiology and the relation of hormones to it; and the award of the Bisset Hawkins medal to Sir George Newman for his distinguished services to public health and for the leading part played by him in the institution of social medical services.

The following appointments were announced:—

Sir Walter Langdon-Brown as Harveian orator, 1936 (the forthcoming Harveian Oration in October next will be delivered by Sir Henry Dale, F.R.S.); Dr. Edward Mapother as Bradshaw lecturer, 1936; Dr. E. L. Middleton as Milroy lecturer, 1936; Dr. R. A. McCance as Goulstonian lecturer, 1936; Dr. John Parkinson as Lumleian lecturer, 1936; Mr. Joseph Needham, Sc.D., as Oliver-Sharpey lecturer, 1936; Dr. J. D. Rolleston as FitzPatrick lecturer, 1936; Dr. R. R. Trail as Mitchell lecturer, 1936; and Dr. Edwin Bramwell as Croonian lecturer, 1937.

The Murchison scholarship was awarded to Dr. W. M. Wilson. Leverhulme scholarships were awarded to Dr. R. L. Noble and Dr. C. C. Ungley; a grant from the same fund was made to Dr. Janet Vaughan to continue the work on which she was engaged before relinquishing her scholarship; and Dr. E. G. L. Bywaters and Dr. L. C. Bousfield were reappointed for six months as Mackenzie Mackinnon scholars.

The following candidates satisfied the Censors' Board and were admitted members of the college:—

Herbert Ernest Appleyard, M.D. Univ. W. Ont.; Alexander Howard Barber, M.B. Birm.; Robert Freeland Barbour, M.B. Edin.; Alfred Ernest Barclay, M.D. Camb.; Cyril George Barnes, M.D. Lond.; William Alexander Caldwell, L.R.C.P. Lond., D.P.M.; Ram Nath Chopra, C.I.E., M.D. Camb. (in absentia); John Francis Coates, M.D. Brist.; Charles Crookenden Cobb, M.B. Oxon.; Hugh Wolfe Corner, M.D. Aberd.; Joseph Edward Debono, M.D. Malta; Maurice Edmund Disney, M.B. Lond.; Guy Arthur Emmerson, M.B. Camb.; Charles Edmund Garson, M.B. Madras; Prashanta Kumar Ghosh, M.B. Calcutta; Vishnu Ramchandra Ginde, M.B. Bombay; Sayed Ahmad Hasan, M.B. Punjab; Mostafa Hashem, M.B. Cairo; Mark Ian Alastair Hunter, L.R.C.P. Lond.; Basappa Sangapa Jirge, M.B. Bombay; Jonas Henrick Kellgren, M.B. Lond.; Michael John Francis McArdle, M.B. Lond.; Thomas Christopher Maling, M.B. Camb.; Malcolm William Miller, M.B. Adelaide; Wilfrid Davison Newcomb, M.D. Camb.; David Neill Parfitt, M.D. Lond.; Arthur Spencer Paterson, M.D. Edin.; Hubert Edward Spencer Pearson, M.B. Lond.; Sydney Augustine Propert, B.Chir. Camb.; Kenneth Robson, M.B. Camb.; Susanta Kumar Sen, M.B. Camb.; Mangaldas Jagjivandas Shah, M.B. Bombay; Edward Peter Sharpey-Schafer, L.R.C.P. Lond.; Patrick McIlroy Smyth, M.B. Camb.; Alan Carruth Stevenson, M.B. Glasg.; Magnus Louttit Thomson, M.B. Aberd.; Henry Arthur Treble, M.B. Oxon.; Ralph Whishaw, M.B. Sydney; Arthur Willcox, M.B. Camb.; Mervyn Williams, L.R.C.P. Lond.; Ralph Paul Williams, M.D. Lond.; Mary Juliet Wilmers, M.B. Lond.; John Caspar Winteler, M.B. Lond., L.R.C.P.; and George Payling Wright, M.D. Oxon.

Licences to practise were conferred upon 205 candidates (183 men and 22 women) who have passed the final examination of the Conjoint Board and have complied with the college by-laws. The following are the names and the medical schools of the successful candidates:—

H. L. Ackerman, Lond.; S. N. Ahmed, Osmania and Birm.;
S. G. Alavoine, Lond.; H. F. Ande
S. O. Aylett, King's Coll.; P. H.
H. D. G. Barnes, Lond.; Mary J.
Beggs, Middlesex; Dipak Bhati
K. O. Black, Camb. and St. Ba
F. L. Bland, Birm.; A. C. Blandy,
M. Blenkin, Roy. Free N. H. Bl
A. S. Bookless, Camb. and Guy's; Fenton Braithwaite,
and St. Bart.'s; W. G. Brander, Camb. and St. Thos.; Margaret C. Briggs, Roy. Free; Margaret Brodigan, Univ. Coll.; A. J. Broomhall, Lond.; E. A. E. A. Brown, St. Mary's; J. L. Brown, Liverp.; K. P. Brown and L. H. Buckland, St. Bart.'s; Kathleen E. Burnell, Roy. Free; E. W. Burstal, St. Bart.'s; H. A. Burt, Camb. and Univ. Coll.; J. H. Caverhill, St. Thos.; H. G. Cereseto, St. Bart.'s; John Charnley, Manch.; P. W. Clarkson, Guy's; J. G. Clothier, King's Coll.; J. H. Cobb, Univ. Coll.; Benjamin Cohen, Charing Cross; G. H. Collier, Manch.; C. D. Coode, Oxon. and Lond.; A. H. Cooke, St. Bart.'s; J. T. Corbett, Birm.; R. F. Courtin, St. Thos.; David Craig, St. Bart.'s; J. M. Cribb, Oxon. and Cardiff; G. F. Crickmay, St. Thos.; Annys M. Cusack, Univ. Coll.; Gilbert, Dalley, St. Bart.'s; V. R. Damle, Bombay; D. V. Davies, Univ. Coll.; D. W. Davies, Cardiff and Middlesex; R. D. L. Davies, Middlesex; W. J. F. Davies, Cardiff; A. B. Dempsey, Lond.; Thomas Denness, St. Thos.; W. H. H. J. De W. De Wytt, Dubl.; L. D. P. Dharmaratne and C. W. Dixon, King's Coll.; R. C. Dolly, St. Bart.'s; E. W. Dorrell, Camb. and St. Bart.'s; J. F. Dow, Camb. and Middlesex; Jean Duncan Whyte, Roy. Free; L. S. Dymond, Cardiff; K. G. Eckersley, Leeds; J. E. Elliott, Guy's; G. D. Elphick, Camb. and St. George's; Maurice Epstein, St. Bart.'s; N. P. Eskell, Camb. and Brist.; E. W. R. Fairley, St. Thos.; Dora J. B. Falconer, Roy. Free; I. A. Feldman, Leeds; Annie Fidler, Manch.; J. G. Field, Brist.; E. L. Fisher, St. Bart.'s; C. S. Ford, Middlesex; I. M. Fradkin, Lond.; O. P. Frank, St. George's; J. H. Mayer Frohlich, Middlesex; J. G. Garman, Birm.; J. St. Garnett, Manch. and Lond.; K. D. Gibson, Camb. and St. George's; B. M. Goldsworthy, St. Thos.; J. F. Goodall, Leeds; C. N. Gosse, Camb. and St. Mary's; D. R. Gray, Camb. and Brist.; Gladys J. Greenhalgh, Roy. Free; C. U. Gregson, Camb. and Liverp.; G. S. C. De S. Gunasekera, Ceylon and West Lond.; Irene G. Hamilton, Brist.; D. R. Hanbury, Middlesex; D. T. K. Harris, St. George's; M. J. Harris, Guy's; W. N. L. Haynes, St. Thos.; Sylvia A. M. Herford, Roy. Free; N. J. P. Hewlings, Camb. and St. Bart.'s; C. C. Houghton, Birm.; D. M. Hughes, Cardiff; T. P. E. Hughes, Oxon. and Middlesex; C. S. Humphries, Camb. and St. Thos.; H. B. Hunt, Birm.; M. I. Husain Osmania and Lond.; N. W. Irish, Guy's; E. C. O. Jewesbury, Oxon. and St. Bart.'s; H. D. Johnson, Camb. and St. Thos.; S. J. Johnson, Univ. Coll.;

S. A. Jones and H. S. Joseph, St. Bart.'s; Solomon Kaufman, Univ. Coll.; A. R. Kelsall, Camb. and St. Bart.'s; T. B. Kenderdine, Birm.; A. R. Kennedy, St. Bart.'s; A. S. Kerr, Liverp.; A. A. Khan, Hyderabad and Lond.; F. J. D. Knights, Middlesex; M. J. Lange, Guy's; R. B. Leech, Camb. and Lond.; P. H. Lenton, Camb. and Middlesex; M. J. Levi, Leeds; Harry Levitt, Charing Cross; J. L. Lewis, Lond.; P. T. Liem, Hong Kong and St. Thos.; C. A. Lillicrap, Guy's; W. L. Lister, St. Mary's; Oswald Lloyd, Middlesex; O. G. Lloyd, Univ. Coll.; J. F. Loutit, Melb. and Lond.; A. C. Maguire, Charing Cross; J. I. C. Mason, St. Bart.'s; D. N. atthews, Camb. and Charing Cross; W. d'A. Maycock, cGill; Ellen Mayer, King's Coll.; W. R. Merrington, Univ. oll.; Samuel Meyers, King's Coll.; I. H. Milner, Charing oss;; C. R. Morison, Camb. and St. Bart.'s; L. F. Muldavin, . Mary's; N. W. N. Murray, King's Coll.; W. G. Murray-owne, Camb. and St. Thos.; M. L. Nairac, St. Bart.'s; B. Neal, Westminster; Howard Nicholson, Univ. Coll.; . P. Niyogi, Calcutta and West Lond.; A. J. Owston, Camb. nd St. Bart.'s; J. G. Parekh, Bombay and St. George's; aude A. Parfitt, Univ. Coll.; W. D. Park, St. Bart.'s; J. N. arker, Manch.; D. N. Parry, St. Thos.; P. S. Patuck, Univ. oll.; Mary M. Paulosky, West Lond.; G. E. Paxon, Guy's; . W. V. Pegge, Camb. and St. Mary's; A. D. Petro, Camb. nd St. George's; E. H. D. Phillips, Camb. and St. Bart.'s; . M. G. Pole, St. Bart.'s; A. R. Pope, Camb. and St. Bart.'s; . J. Porter, Camb. and Lond.; I. H. Premdas, St. Bart.'s; . S. Price, Birm.; W. A. Pritchard, Univ. Coll.; D. A. Pro- hero, St. Bart.'s; S. A. Qadri, Osmania and Birm.; B. K. R. ao, Mysore and Lond.; R. G. Record, Birm.; S. J. R. Rey- olds, Camb. and Charing Cross; E. A. Richards, St. Thos.; . E. O. Ringdahl, St. Bart.'s; Bernard Roberts, St. Mary's; ilda Roberts, Liverp. and West Lond.; R. E. Rodgers, Camb. nd St. Thos.; P. W. D. Russell, St. Thos.; J. P. Salkield, niv. Coll.; R. G. Samuel and R. S. Saxton, Camb. and St. Bart.'s; Moses Schlaff, St. Bart.'s and West London; James chofield, St. George's; P. G. Scott, Camb. and Univ. Coll.; Coleman Segalov, King's Coll.; Girija Nath Sen, Calcutta and t. Bart.'s; H. J. Sherren, Camb. and St. Thos.; S. G. Shippard, King's Coll.; N. S. Shtetinin, Manch.; Aubrey Smiter, St. Mary's; G. C. Smith, St. George's; Elsie M. Smyth, Univ. Coll.; S. J. Stein, King's Coll.; Eunice F. Sterling, Rochester nd Roy. Free; J. M. Stewart, St. Bart.'s; Abraham Stoller, Univ. Coll.; D. W. I. Thomas, St. George's; H. C. Thomas, Lond.; S. M. Thompson, Camb. and Leeds; J. D. B. Vaile, St. Thos.; W. H. Valentine, Camb. and St. George's; Constance M. Vallange, West Lond.; P. W. Vilain and Alan Wardale, King's Coll.; Melville Watkins, St. Mary's; Elizabeth H. Western, Camb. and King's Coll.; B. L. Williams, Camb. and St. Thos.; Eugénie L. Willis, Camb. and Roy. Free; A. B. Wilson, Manch.; J. S. H. Wilson, St. Bart.'s; G. N. M. Wishart, Manch.; Rowena Woolf, Roy. Free; G. F. Wright, Camb. and St. Thos.; and Hyman Yarrow, St. Bart.'s.

Royal College of Surgeons of England

An ordinary meeting of the Council was held on July 25th, with Sir Cuthbert Wallace, the president, in the chair. Mr. Thomas William Widdowson was elected a member of the board of examiners in dental surgery. Prof. G. A. Buckmaster and Mr. Gordon-Taylor were appointed examiners for the forthcoming primary examination in India for the fellowship. The president stated that, after the primary fellowship examination, which will be held at the end of this year, the next examination in India will not take place until 1937.

The following hospitals were approved with the posts specified for recognition for the six months' surgical practice required of candidates for the final examination for the fellowship:—

London.—The West London Hospital (3 house surgeons); Woolwich and District War Memorial Hospital (for two years, senior resident medical officer and one house surgeon).

Provinces.—Radcliffe Infirmary, Oxford (resident surgical officer and one house surgeon; Cornelia and East Dorset Hospital, Poole (for two years—one house surgeon); Swansea General and Eye Hospital (senior resident medical officer and 3 house surgeons).

Diplomas in anæsthetics were granted to the following under the special conditions of the regulations, jointly with the Royal College of Physicians:—

H. E. G. Boyle, Robert Brown, J. M. Clark, F. T. Evans, C. F. Hadfield, Frederick Whalley.

The following diplomas were also granted jointly with the Royal College of Physicians:—

D.O.M.—K. B. Armstrong, F. G. Fenton, N. W. Gardener, P. K. Guha, M. A. L. Hassouna, T. H. Hodgson, R. H. Hucknall, G. A. Jamieson, Hermann Lipschütz, M. C. Mankodi, J. R. Mutch, Samuel Pearlman, Violet M. Phelps, H. L. Shankman, S. K. Sledge, A. McL. Thomson, T. H. S. Tizzard, and S. D. H. D. Wallis.

D.M.R.E.—Christine C. Abernethy, D. Hugo, and D. J. Thomas.

Diplomas of membership were granted to the candidates named in the report of the meeting of the Royal College of Physicians.

Diplomas were also conferred jointly with the Royal College of Surgeons on those candidates named in our issue of June 22nd, p. 1476, July 20th, p. 167, and in this issue under the Royal College of Surgeons.

Dr. Barugh Spearman, chief medical and health officer for Grenada, has been appointed a member of the Executive Council of the island.

University College Hospital Medical School

The Bilton Pollard fellowship has been awarded to Dr. J. C. Hawksley.

Epsom College

St. Anne's Scholarship.—The council will shortly elect a girl to a St. Anne's Scholarship of £110 a year, tenable at an approved boarding school. Candidates must be not less than nine years of age on July 30th, 1935, and must be orphan daughters of medical men, who, for not less than five years have been in independent practice in England or Wales. Application must be made by Oct. 22nd on a form to be obtained from the secretary of the College, 49, Bedford Square, London, W.C. 1.

Middlesex Hospital Medical School

On July 24th this hospital celebrated the hundredth anniversary of the foundation of its medical school. In the afternoon the Earl of Athlone, chancellor of the University of London, visited the hospital to present the prizes to the students and nurses. Prince Arthur of Connaught presided and among those present were Lord Dawson, P.R.C.P., Sir Cuthbert Wallace, P.R.C.S., and Dr. J. S. Fairbairn, P.C.O.G. Mr. A. E. Webb-Johnson, treasurer of the medical school, speaking on the "First Hundred Years," described the steady progress which had taken place in the science and practice of medicine during this time; thousands who had watched the Jubilee procession would not have lived to see it but for the application of newly acquired medical knowledge. He reminded his listeners of the alliance of the medical school with the University of London, and of the many benefactors who had helped it in recent years—including Bland Sutton, the Joels, John Astor, and S. A. Courtauld. Lord Dawson and Sir Cuthbert Wallace congratulated the school on behalf of the Royal Colleges. Dr. H. E. A. Boldero, the dean of the medical school, announced that two scholarships of £100 each were being founded by the council for London University men who had done their preclinical work. Mr. E. W. Meyerstein had given £3000 to endow one of these scholarships, and had also given the school £20,000 to add to the accommodation available for students.

In the evening Prince Arthur of Connaught and Mr. Courtauld received a large company in the board-room of the school. A display of scientific exhibits had been prepared in the different rooms and in the first section, devoted primarily to radiotherapy, there were "electromagnetic surprises," "radium luminosities," an instrument which tracks down missing radium, and a model of the projected radiotherapy department. In another section apparatus for artificial respiration attracted much attention, and there were also demonstrations of the electric currents produced by heart-beats and of methods used in the examination of foods, drugs, stimulants and soaps, historical exhibits were arranged in the dean's room, and engravings and photographs in the senior common room. Prof. Samson Wright also gave several exhibitions of a cinematograph film of the circulation of the blood, while the temperature of the ordinary air intensified the audience's appreciation of Prof. W. B. Tuck's demonstration of the freezing properties of liquid air. (Incidentally, his frozen whisky had so much success that only the licensing laws, he averred, prevented him from promoting a new line of the stop-me-and-buy-one business.) In the museum upstairs microbes were treated with thoughtful concern, one of the tables being reserved for "delicacies to tickle the bacterial palate." Other exhibits in the same section included blood pictures in disease and blood tests in infection and fevers. Elsewhere the visitors were shown examples of the use of biochemical analysis and tests in medicine, the observation of cell metabolism, and the determination and application of the basal metabolic rate. A fifth section displayed the equipment of the X ray diagnostic department, which is said to be capable of handling 30,000 to 40,000 cases per annum. It includes an X ray pathological museum with ten sections of viewing-boxes, each devoted to a particular part of the body.

Royal Dental Hospital

The prize distribution and conversazione of the Royal Dental Hospital and London School of Dental Surgery, will be held at the hospital (32, Leicester-square W.C.), on Friday, Oct. 4th, at 8 P.M. when Sir Francis Dyke Acland, will preside.

London Hospital Medical College

The post-graduate course for former students of this school will be held from Oct. 16th to 19th. Further particulars may be obtained from Dr. A. E. Clark-Kennedy, the sub-dean, the London Hospital E.1. The annual, dinner for all past students of the hospital will take place at the Trocadero Restaurant, Shaftesbury-avenue, W., on Thursday, Oct. 17th, at 7.30 P.M.

University of Hong Kong

Mr. W. C. W. Nixon, F.R.C.S, assistant obstetrical surgeon with charge of out-patients at St. Mary's Hospital, London, has been appointed professor of obstetrics and gynæcology in the University, and consultant to the Government Civil Hospital, Hong Kong.

Royal Society of Medicine

The William Gibson research scholarship for medical women has been awarded to Dr. F. Stephen-Lewis of the University of Witwatersand. Dr. Stephen-Lewis proposes to carry out a reseerch on the chenistry of South Africann plants, and particularly those used by the natives as medicines. She will also investigate physiological data for the various native tribes.

International Union against Tuberculosis

Delegates from twenty countries attended a council meeting of the union at 66, Boulevard St. Michel, Paris, on July 10th and 11th, under the chairmanship of Dr. Piestrzynski, under-secretary of state for Poland. The administrative meeting was devoted to the preparation of the programme of the Lisbon conference on Sept. 8th–10th, 1936, when the principal subjects of discussion will be "Radiological aspects of the pulmonary hilum and their interpretation" (to be opened by Prof. Lopo de Carvalho, Portugal); "Primary tuberculous infection in the adolescent and the adult" (Dr. Olaf Scheel, Norway); "The open case of tuberculosis in relation to family and domestic associates" (Sir Henry Gauvain, Great Britain). At the scientific meeting Prof. Lyle Cummins (Cardiff) occupied the chair, and Prof, Madsen (Copenhagen), submitted a report on "Tuberculin Standardisation and Tuberculin tests." Dr. Kendall Emerson, managing director of the National Tuberculosis Association, gave an account of the work of Dr. Long and his collaborators, who claim to have isolated the active principle of tuberculin. The relative merits of Pirquet's cuti-reaction and Mantoux's intradermal test were considered; the majority of the French speakers expressed a preference for the former, while their colleagues from other countries preferred Mantoux's test. They all agreed on the advisability of adopting a standard tuberculin and a uniform tuberculin test.

La Semaine Medicale Internationale

An international medical week has been organised by the Schweizerische Medizinische Wochenschrift at Montreux from the 9th to the 14th September under the control of a distinguished Swiss committee. The programme opens with a reception on the evening of Sunday, Sept. 8th, in the Montreux Casino. Important discussions on general subjects have been promised for the ensuing days, and such authorities as Sir Henry Dale and Profs. Abderhalden, Sigerist, de Quervain, Sanarelli, and Lemierre, will take part in them on Monday, Tuesday, and Wednesday. On Thursday debates on neuroses and failures of growth in children will be followed by a visit to the Nestlé factory. On Friday the treatment of cancer will be discussed from many angles, special attention being paid to radiotherapy. The sittings will take place in the mornings in the Montreux Palais, and receptions are planned at which ladies accompanying the congressists will be welcomed, a special ladies' committee having been instituted. Further information can be obtained from the Sekretariat der Internationalen Medizinischen Woche in der Schweiz, Klosterberg 27, Basel.

Advisory Committee on Nutrition

The Minister of Health and the Secretary of State for Scotland have appointed Dr. T. W. Wade, of the Welsh Board of Health, and Mr. E. H. H. Lloyd, secretary of the Market Supply Committee, to be members of the new Advisory Committee on Nutrition. The constitution of the committee was announced in our issue of June 8th (p. 1364).

Medical Charitable Society for the West Riding

The annual meeting of this society was held at Huddersfield on June 30th, Dr. D. L. Cairns presiding. Forty-four applications came before the meeting and, all being found deserving, grants were made amounting to £2,283. To mark the occasion of the King's Silver Jubilee a gift was made to each recipient of 10 per cent. of the amount of the grant allotted. Of the recipients, nine had already been given twenty or more grants, three had been given thirty or more grants, and one applicant had received no fewer than 53 grants. One of the annual subscribers died in the year 1883; in respect of his membership the first application was made by one of his sons just fifty years after, and was at once met by an emergency grant and by an ordinary grant at the next annual meeting. Since the inception of the society grants have been made amounting to £95,726 and £49,670 expended in the purchase of securities. A grant of £50 was made to Epsom College; under the new rules, money can now be voted by the society for foundation scholarships at the College. The objects of the society are to help any of its members who are disabled by illness, accident or age and who have not adequate means of support; to help the widow or children of a deceased member, who may at any time require assistance; under certain restrictions, to extend help to the relatives of a deceased member who may have acted as his housekeeper, and finally to contribute to the expenses of the education of children of members or of deceased members in cases where it is deemed advisable to do so.

Appointments

Marshall, S. F., M.B., M.R.C.P. Lond., has been appointed Pathologist to St. Mary's Hospital for Women and Children, *Plaistow*.

Pratt, F. W. M., M.S. Durh., F.R.C.S. Eng., Hon. Surgeon to the Willesden General Hospital.

Selbourne, Hugh, M.D., M.R.C.P. Lond., Medical Registrar at the Southend-on-Sea General Hospital.

Spencer, S. L., M.B. Sydney, F.R.C.S. Eng., Surgical Registrar at the Southend-on-Sea General Hospital.

Trail, R. R., M.D. Aberd., F.R.C.P. Lond., Hon. Physician to Papworth Village Settlement, Cambridge.

Births, Marriages, and Deaths

BIRTHS

Dockray.—On July 22nd, the wife of Edgar Dockray, M.B. Edin., Cobham, Surrey, of a daughter.

Geldard.—On July 20th, at Sheringham, Norfolk, the wife of H. Colin Geldard, M.R.C.S. Eng., of a daughter.

Gipson.—On July 22nd, at Welbeck-street, the wife of T. Gipson, B.Chir. Camb., of a son.

Walker.—On July 21st, at Wolverhampton, the wife of Robert Milnes Walker, M.S. Lond., F.R.C.S. Eng., of a daughter.

MARRIAGES

Cutlack—Bowen.—On July 17th, at St. Andrew's Church, Cardiff, A. Russell Cutlack, M.R.C.S. Eng., to *Gwendoline* Ellen, daughter of Mr. W. Bowen, Treharris.

DEATHS

Bennett.—On June 28th, at Gerringong, New South Wales, George Herbert Bennett, M.R.C.S. Eng., *son* of the late John Nicholas Bennett, of Plymouth, in *his* 76th year.

Chill.—On July 23rd, Edwin Albert Chill, O.B.E., M.D. Edin., of Battle, Sussex.

Davidson.—On July 13th, at Murree, India, Robert Davidson, M.D. St. And., Lieut.-Colonel, R.A.M.C., aged 48 years.

Jones.—On July 26th, at Cambridge-street, W., William Howard Jones, M.B. Lond.

Le Riche.—On July 25th, at Worthing, Philip John Le Riche, M.R.C.S. Eng.

Sanderson.—On July 25th, at Basra, Iraq, Arthur Frederick Sanderson, M.R.C.S. Eng., son of Walter Sanderson, of Kew Gardens.

Wallace.—On July 23rd, Hygeia Leigh Josephine Wallace, M.R.C.S. Eng., of Plowden Buildings, E.C.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

NOTES, COMMENTS, AND ABSTRACTS

"GRAVEYARD" WALKER—A FORGOTTEN BENEFACTOR

A curious obriquet with which to pass through and out of life. The owner thereof, though now forgotten, was, despite the strangeness of his appellation, a significant benefactor of his fellows, and earned his title, but little other recognition, by exposing grievous abuses and by strenuous agitation until remedy was effected. Sir John Simon, the first Medical Officer to the City of London, and later of the Board of Health and Local Government Board, in detailing some victories of preventive medicine recalls how the names of the protagonists have been forgotten, and ponders:

> "Doubtless this is so: but let the noble compensation be noted that often the thoroughness of a reformer's victory is that which most makes silence of the reformer's fame."[1]

Of few are these words so true as of "Graveyard" Walker. Who was he, and why should we endeavour to rescue him for a brief space from the oblivion of time?

George Alfred Walker was born in Nottingham in 1807, studied medicine in London, sojourned for a time in Paris, returned to London and practised his profession in Drury Lane, and died in retirement in Wales in 1884. His working life was consumed by one passion, that of the reform of the condition of burial places, a reform to which he was stirred in quite early years by sights which he witnessed in his native city. The subject is not a pleasant one. There may be room still for improvement in methods of disposal of the dead, but the conditions which prevailed a century ago are to-day unbelievable. Burial grounds, of limited space, often of private ownership, were situated amidst congested populations and the constantly increasing demands upon their capacity resulted in conditions which offended reverence, decency, morals and health. It would be ghoulish to dwell upon the abhorrent details which Walker accumulates in his various writings, but anyone who cares to study these may sup his full of horrors.

Sir John Simon, in reporting to the City of London, expressed the theme in forceful phrasing:

> "Nor can I refrain from adding, as a matter claiming attention, that, in the performance of intramural interment, there constantly occur disgusting incidents dependent on overcrowdedness of the burial ground; incidents which convert the extremest solemnity of religion into an occasion for sickness and horror; perhaps mingling with the ritual of the Church some clamour of grave-diggers who have miscalculated their space; perhaps diffusing amidst the mourners some nauseous evidence and conviction that a prior tenant of the tomb has been prematurely displaced, or that the spade has impatiently anticipated the slower dismembering of decay."

Dickens too, eager always to attack abuses, has drawn a graphic picture in "Bleak House":

> "'There,' says Jo, pointing, 'over yinder. Among them piles and bones and close to that there kitchen winder! They put him very nigh the top. They was obliged to stamp upon it and get it in. I could unkiver it for you with my broom if the gate was open. That's why they lock it, I suppose. It's always locked. Look at the rat!'"

And Walker placed on the frontispiece of his "Gatherings in Graveyards" some lines from another contemporary, Henry Kirke White, described in the "Dictionary of National Biography" as a poetaster, but in memory of whom the "Remains of Henry Kirke White," attaining to 10 editions, was compiled by Southey.

> "And who would lay
> His body in the city burial place,
> To be thrown up again by some rude sexton
> And yield its narrow house another tenant,
> Ere the moist flesh has mingled with the dust
> Ere the tenacious hair had left the scalp,
> Exposed to insult lewd, and wantonness?
> No, I will lay me in the village ground;
> There are the dead respected."

Well might Walker exclaim:

> "It is quite certain that any attempt to draw a parallel between the ancient heathen and the modern Christian in this respect would be infinitely to the disgrace and dishonour of the latter."

Walker had been stirred to revolt on this subject by scenes witnessed in early days, by further experiences in Paris, and his reforming zeal was continually moved by the loathsome evidence which pressed upon him in the densely-populated neighbourhood amidst which he later practised. He wrote books, of which "Gatherings from Graveyards," published in 1839, was the earliest; he lectured on his subject; he aroused public interest, and was mainly responsible for the appointment of a Select Committee of the House of Commons in 1842. Later, government inquiries and reports followed, the reform received the powerful advocacy of Chadwick, and ultimately in 1852 there was placed on the Statute book an Act to amend the Laws Concerning the Burial of the Dead in the Metropolis, the provisions of which were in the following year extended to England. These enactments opened the way for the remedy of the worst abuses, and were the forerunners of later legislation.

Thus "Graveyard" Walker lived to witness the fruit of his labours, but it is probable that none now ever pause to pay him tribute. After his death a contributor to *The Athenæum* of July 12th, 1884, wrote:

> "Others who took up the cry after him obtained the reward. His sole recompense was in witnessing the triumph at last of the cause he had so long and energetically advocated."

AFTER-CARE OF QUETTA CASUALTIES

After the earthquake of May 31st at Quetta the cases of severe fracture were transferred to the Mayo Hospital at Lahore, where it was possible to segregate in separate wards the fractures of different regions, spine, pelvis and femur. Balkan frames fitted with adjustable pulleys, weights and traction cable were available for all cases. Many fractured thighs were treated by stainless steel pins, transfixing soft tissues and bone, attached by a stirrup to the traction cable, the limbs being supported in flannel slings on Braun's cradles. In other cases the Kirschner wire was used, with the appropriate design of stirrup for this variety. Lieut.-Colonel W. Ross Stewart, I.M.S., reports that in no single case was there a sign of septic infection of the soft tissues or bone, and the patients were invariably comfortable. Although most of the cases were put up under local anæsthesia perfect alignment was attained. Many cases of fractured pelvis were treated by pin or wire traction applied to both lower limbs. "Aeroplane" splinting combined with transfixion and spring traction was used for fractures of the upper arm, allowing of movement of surrounding joints with no disturbance of alignment. Fractured spines were all reduced on a special table before splinting. Colonel Stewart notes that, although a host of workers had contributed to organise this surgical clinic and to improvise apparatus, there were none of the usual features of improvised equipment. Lieut.-Colonel D. H. Rai, I.M.S. and Lieut.-Colonel J. J. Harper Nelson had much to do with the provision of this surgical unit and the expansion of beds, but Colonel Stewart attributes the exceptional standard reached to the vision, energy, and skill of Lieut.-Colonel V. R. Mirajkar, I.M.S., superintendent of the and he who sweats too much. He whose habits are dirty itches, and he who is cleanly to a fault. It may be presumed that not all tramps itch—or not distressingly to themselves—but my Lady Vere de Vere certainly does not always escape by the frequency and complexity of her toilet. Pruritus may be general or local. It is the merest tyro who supposes that general pruritus is due to general causes and local pruritus to local causes. I am quite sure that pruritus ani, one of the most tiresome forms of pruritus, may be of entirely general origin, and this *pace* the proctologist, who, not unnaturally, takes the very opposite view and believes all cases arise from local causes. On the other hand a single acarus in its burrow may give rise to very extensive pruritus. When the cause is a general one as, say, in gout, the site of a local pruritus may often be determined by some local defect, but this is frequently so trivial as to go often entirely undiscovered. I will allow the dictum that if a pruritus be general the cause is more likely to be general than local, but my experience warns me strongly against the converse statement, that a local pruritus is more likely to depend upon a local, than upon a general, cause.

---

[1] English Sanitary Institutions, p. 124.

General Causes of Itching

Amongst the more or less obvious, and serious, general causes of pruritus are diabetes, uræmia, and leukæmia. Jaundice is another, but not necessarily such a serious, cause. Pruritus in Hodgkin's disease is less known, but it is sometimes such a marked symptom here that its presence may be helpful in diagnosis, seeing that it does not seem to occur in that form of tuberculous adenitis which not infrequently conflicts with lymphadenoma. Pruritus occurs in hyperthyroidism, both with, and without, skin lesions. It also occurs in pernicious anæmia and in other conditions involving hæmolysis. I have met with two very troublesome examples of it after splenectomy, accompanied, in one of the cases, by urticaria. Though it is usual in these days, when the microbic hypothesis still holds such sway in our minds, to search for "focal sepsis" in all cases of generalised pruritus, convincing evidence of the causative association of the two conditions is less often forthcoming than is usually taught. The most common forms are dental and gall-bladder sepsis and chronic colon bacillary infection of the urinary tract. Pruritus must be quite unusual in tonsillar sepsis and in sinusitis.

Since the term "intestinal toxæmia" connotes at least three different pathological processes, to say this is a common cause of pruritus tells us nothing definite. (i) The ingestion of certain substances to which patients are "sensitised" is very likely to cause pruritus, a matter to which I shall return later. (ii) Bacterial sub-infection of the bowel may cause pruritus, but the association in a causative sense is almost impossible to establish. (iii) The doctrine of "copræmia," meaning the absorption into the blood stream of certain retained products of fermentation from food principles, has never been submitted to scientific research. Even the statement, so commonly made, that constipation is a frequent cause of pruritus, may be challenged. I have met with several patients who developed pruritus after fiddling with their bowels, though it is extremely difficult to say, in such cases, if the itching is the result of an abnormal degree of absorption from a more frequently denuded mucous membrane, or of the chemical agent used as an aperient.

Of all the general causes of pruritus, however, the most common is "gout." Did not an ancient physician call itching "the lisping of the gout?" The word is, as we know, somewhat *démodé*. But to rid medical nomenclature of the word "gout" does not rid medical practice of the gouty patient. Acute articular gout is, no doubt, far less common than it formerly was: so much less common indeed, that when it appears it not seldom fails of recognition. But goutiness is as common as ever, if not commoner. But what *is* gout? Is it an entity? Is it one thing or is it several things? The time is not ripe, even now, for answering these questions. We know what gout is *not*: it is not poisoning of the body by uric acid, still less is it due to a deposit of biurates in the tissues. It seems probable that there is a basic pathological process in all cases, but the vagaries introduced by the individual equation are so numerous and so important, that we must almost consider each man's gout to be his own, and study it as such, if we are to achieve a therapeutic success. What structures in the body are mainly concerned in this postulated basic mechanism is largely a hypothetical question. That the liver looms large in this field seems probable. Yet we may find, later on, that the dominant tissue is not this, but something more subtle, and not as yet revealed. The discovery of the reticulo-endothelial system and its influence upon the blood-forming organs suggests strongly that we have by no means exhausted the discovery of tissues and tissue functions by combining histological with metabolic research.

Allergy

The relation of goutiness to allergy is as yet undetermined but that there is some close association seems highly probable. The concept of allergy, originally much too limited in its application, has probably become to-day much too unconfined. Or perhaps it is more true to say that the notion has far outstripped the facts—a way that all new notions have. Richet's fundamental observation of the phenomenon which he called *anaphylaxis* gave clarity and cohesion to a large number of clinical experiences. But until we know much more about the exact happenings in the production of this state of sensitisation we cannot say how wide its application may be. It seems probable that in the case of the skin the doctrine of allergy is applicable to many more conditions and to many more patients than is generally supposed. Urticaria and its ally angeioneurotic œdema, with some forms of eczema, especially in children, appear to cover the allergic group of skin affections in most books dealing with these matters. Just as the dramatic syndrome termed asthma, with its ally, hay-fever, seem to absorb the same attention in the respiratory field. I think most cases of lichen urticatus should be included in this group, and in this connexion I would add, incidentally, that this disease is by no means confined to children, as many authors suggest. I am equally confident that a great deal of pruritus, both general and local, whether associated with demonstrable lesions or not, also deserve inclusion, in addition to the itching disorders already mentioned.

The fact that serum-sickness has frequently an incubation period of 8–10 days goes to show that considerable latency may exist between cause and effect in pruritic diseases, though it is true to say that when the irritant is inhaled, or is absorbed from the alimentary tract, the evidence of sensitisation is usually much more rapid. There are some general considerations of importance which suggest themselves in this connexion. (i) It is too often asserted, and dogmatically, that the allergic patient is sensitised specifically. But there are many individuals who are sensitised against a large number of substances, and this fact introduces great difficulties both in diagnosis and in treatment. (ii) The question whether the irritant in allergic patients is always a protein is supposed to be settled in the negative, the experience of drug idiosyncrasies being adduced in support. But the argument is by no means so simple as this. If drugs do good indirectly, as we know many do—the arseno-benzol group for example—it is just as likely that they do *harm* indirectly, setting free some protein fraction in the circulation to produce allergic effects in the skin or elsewhere. (iii) Not only are some individuals sensitised to a number of different substances, *they may show their allergic tendency* n a number of very different ways. And those ways o not always alternate, as do the classical examples f eczema, asthma, and certain forms of arthritis. he most catholic example amongst my own patients a man who became sensitised after small-pox accination with suppuration under the scabs, at the ge of 25 years. He suffers from both paroxysmal hinorrhœa and stuffy nose. He has had several ttacks of acute articular gout, being awakened in he early morning with an excruciatingly painful, pink, lossy and swollen foot. A small dose of medinal keeps him awake all night with severe urticaria. Beer, chicory, the whisky of some of his friends but not all, and he keeps a list of these), and some ngredient in Worcester sauce which is not in any of ts competitors keep him equally restless and sleepless with intense pruritus ani. He was once stung by a wasp and collapsed instantly, requiring volatile stimulants and other restoratives.

The Nervous Factor

The last of the general factors to touch upon but, in some respects, the most important, is the nervous factor. The overlap of the nervous factor with both gout and allergy is considerable. But the influence of the nervous system upon metabolism is too large a subject for this address if, indeed, it be not too large a subject for any single address. The introduction of the word "neurotic" by Quincke into the designation of the disease which bears his name is fully justified by a study of the cases. Even though the allergic factor in this and other skin diseases is established, this does not minimise the importance of recognising the element of nerve instability in many of the patients affected. Sometimes this instability is central, sometimes it is autonomic, sometimes both. Here again, each case must be taken on its merits. We must avoid the stigma that the use of the word "nervous" *often conveys to a sensitive patient*; or if we use the word, or condone it, we must explain that it by no means necessarily reflects upon the patient's behaviour or has any moral significance. If confidence be needed, we may cite examples of men and women who have made great contributions to life and yet who suffered from some form of neurosis. But the patients who possess a central nerve instability, who are psychotic in fact, present a problem of their own. To help them we cannot know too much about them, soul as well as body. To have it said of a medical man: "I found myself telling him everything" is a good compliment. And to create the atmosphere that makes self-revelation easy, indeed, makes self-revelation inevitable, is the acme of good doctoring. If, now, the process can be continued and completed by the same doctor, in the same room—even if the exigencies of practice do not make it possible that it should be continued at the same time—without the break introduced by an appointment made at a new address, with a new doctor bearing the ponderous title of psychotherapist, so much the better. Organic diseases of the nervous system lead to rather surprisingly few instances of pruritus, and it is only want of care in attending to the patient's description of his dysæsthesiæ that leads to a misinterpretation of these in terms of pruritus in (say) an early case of subacute combined degeneration.

Of local causes of pruritus I do not propose to treat in detail. Charles Lockwood, a man to be remembered as much for his gift of teaching as for his poineer work in aseptic surgery, was wont to exhort his pupils "always" to "examine the part the patient complains of." The injunction seemed superfluous, almost silly, and yet the most careful amongst us are now and then found to be negligent of this very trite advice. The reminder applies with tremendous force to affections of the skin, and to remember it in a difficult case of pruritus saves us from many a pitfall. All the same, it is pertinent to repeat here what I have already remarked, that there are few cases of local pruritus in which a general factor is not present.

Treatment

I have sometimes been as guilty as Lockwood in the matter of *obiter dicta*, and I do not disclaim plagiarising the description of his art attributed to Demosthenes, by saying that the most important thing in treatment is diagnosis, the next most important thing is diagnosis, and the third most important thing is—diagnosis. To no complaint, again, does this truism apply more than to pruritus.

Having unearthed the ætiological factors, both local and general, we must deal with these as patiently and as persistently as possible. Always facing the patient with the imperative need for his coöperation. We cannot live his life for him; it would not help him in the end if we could. It is sometimes necessary to get a clear issue on the point whether it is really worth his while being free from his trouble. How much self-indulgence, for example, is he prepared to give in exchange for comfort to his skin? Here is *not a question of his skin as symbolical of his life; we know about that; we know that "all that a man hath will he give for his skin."* What he is prepared to give to avoid pruritus is quite a different proposition. In the majority of cases the truth remains that a man can have almost anything he wants in life if he is prepared to pay for it. Here he is called upon, not infrequently, to help in the diagnosis. If he be allergic he must keep a food diary, *and take some trouble about it, too. He* must brace his mind to the questionnaire put to him by his doctor, and he must be loyal in carrying out the régime prescribed for him, not omitting some item because it seems to him to be trivial or devoid of meaning. We soon discover the degree of his disability by his reaction in these matters.

Most patients, and quite reasonably, prefer artificial methods of therapy to natural methods, and those methods that have kinship to "direct action" in politics are the most attractive of all. But in the case of pruritus we have not got many remedies of this class on hand. Or certainly not for permanent, *as against temporary*, relief. In the allergic patient, for example, our available methods of desensitisation, both specific and non-specific, are at present very disappointing. In theory they are most convincing, in practice not so. Just as "knowledge comes but wisdom lingers," so does theory arrive but practice lag behind. And so we find that avoidance of the peccant substance, whether in the food or in the air, or the clothes or the furniture, though more bothersome, is more effective. But this means care and trouble and—dare it be said?—intelligence. And, as I say, the question arises: is it worth while? After all, just as "life is more than meat and the body than raiment," so a bout of itching, even to the degree of suggesting the inquiry "what is the doctor doing about it?"—and most of the minor disturbances in life tend to raise the query in this soft age—may be a very mean payment for a good dinner, a cocktail or sherry party or the vanity of toilet powder and a fur boa. The position should be faced clearly and as clearly stated. Our function is to explain and guide, not to govern and control.

There are few cases of pruritus for which we cannot do a good deal and fewer still for which we cannot do something. I do not think there are any for which we can do nothing. The most intractable cases of all are those instances of diffuse itching which go by the depressing name of "senile pruritus." The use of this term stultifies our efforts at diagnosis, it does not add to our knowledge. In quite a number of these cases the patient is in many respects young, and not old, for his years, is of the alert and active type, and a close examination of his skin does not reveal evidence of that atrophy which is too often assumed to be present. On the other hand we frequently see skins that are definitely atrophied, in still older patients, with no such disability. The other statement, so frequently made, that the subjects of so-called senile pruritus are troubled by "imperfect metabolism" is another assumption, unhelpful from its very vagueness. Every one of these cases must be taken on its merits and thoroughly investigated. Of the underlying morbid conditions present in them, goutiness, an unstable nervous system and focal sepsis are perhaps the most common. The question of septic teeth involves the physician in the difficult dilemma that he cannot promise an adequate return from extractions, yet he knows that to follow established principles is his only safe procedure. Goutiness demands careful and individual treatment: n general advice can be volunteered. The most usef drug in the nervous type of pruritus is luminal, in a small a dose as produces effects. An older remedy i cannabis indica, but the drug seems to lack potenc these days or, if trouble be taken to secure an active preparation, the patient is prone to complain of odd symptoms that alarm him—and he is too often the sort of person who is very easily alarmed

When, in a difficult case of pruritus, we have done our utmost in removing all possible local irritants and congestions; when we have placated the unstable nervous system; when we have brought the swinging metabolic pendulum to rest; when we have exploited the doctrine of allergy to the full; when we have tracked down focal sepsis to the last ditch; the pruritus may still persist. We have treated the disease and now our traditions, as well as our duty, demand that we treat the symptom, in this event itself the disease. To talk of unguents and lotions to an audience of dermatologists would indeed be taking coals to Newcastle; would add the insult of supererogation to the injury already done to your patience. I may be excused, however, for adding a few words concerning X rays, partly because the tendency to employ this therapeutic measure is increasing, partly because it is at times so strikingly effective, and partly to inquire if there be any dangers in the method.

Results of an Inquiry

So that what I may say on this subject shall not be only the result of my own experience, I recently canvassed five dermatologists and five radiologists for their views. I naturally chose colleagues whose practice is extensive and whose judgment I knew to be reliable. A composite analysis of their answers, for which I take this opportunity of thanking them very cordially, confirms my own opinion on the subject. It will not be a surprise to learn that the radiologists are, on the whole, rather more enthusiastic concerning this therapeutic measure than are the dermatologists. Nor that the degree of enthusiasm amongst both groups varies considerably.

I will state the conclusions of these experts in a few brief sentences:—

1. There is general agreement that in pruritus ani and pruritus vulvæ, and in other forms of localised pruritus, X rays frequently produce marked relief. The figures vary from 90 per cent. to 60 per cent.

2. There is general agreement that "cure," by which I understand is meant complete cessation of the symptom, occurs in a considerable number of cases. The figures vary around 50 per cent.

3. There is general agreement that in diffuse, as against local, pruritus, the treatment fails.

4. The majority use small doses, but a minority states emphatically that heavy doses are more satisfactory.

5. The note of caution is sounded by most, and the note is, again not unnaturally, rather louder in the case of the dermatologists than in that of the radiologists. One of the latter gives as his working rule: "if no response follows the first treatment, proceed cautiously; if no response follows the second, discontinue." He adds: "proceed with extreme caution when patients have already had X ray or radium treatment."

6. Without exception the derma upon the importance of a comple radiologists do likewise, either assumption th their general med already borne in mind the great i point.

7. It is not without significance th logist who was the first physician in skin diseases by X rays writes the of the letters with regard to the submitted to him.

Where the experts find it so diffi unanimity it is excusable for the non-exp Perhaps the truth lies here, as it does many therapeutic measures: be bold, not too bold.

THE COD-LIVER OIL TREAT OF WOUNDS

By John P. Steel, M.D. Edin.

MEDICAL SUPERINTENDENT, SMITHDOWN ROAD H
LIVERPOOL

THE annotation in THE LANCET (1934, calling attention to the use of cod-liver oil treatment of burns and septic wounds by Wilhelm Löhr of Magdeburg, was of sufficie portance to warrant a trial of the metho described. Burns are seldom received at a hos without first-aid treatment having been given out usually in the form of an *oily dressing* applied to burnt area; for this reason the tannic acid met is not often applicable without extensive skin to requiring in many cases a general anæsthetic. Pic acid is also extensively used for its analgesic prope ties, and tannic acid is not readily applicable *on* suc

a surface. Where skin toilet was not YMENT

The application of cod-liver oil seem
method and so generally useful that it
to treat minor burns in an endeavour t
value, and the comparison was very e "industrial
tannic acid and the other oily dressings. which compen-
panying illustrations will show that war neuroses"
decided that the use of cod-liver oil was the effects of
not only in burns of a minor degree, but te have also
of much greater extent and penetrat years. There
in fact, been so successful that it is n conditions in
routine here to treat any burn with cr indispensable
oil. The main advantage is that, on a maintaining
matter what has been applied outside it is ial influences
to undertake any extensive skin toilet be who respond
dressings. e what other

At first it was thought that cod-liver these few, as
into an ointment with some waxy base nences, emain
in closer contact with the burnt area, bu was soon
found that the dressing, when the time can for renewal,
was either dry or inclined to draw th granulated
tissue away with the remains of the waxy ointment.
To overcome this difficulty, lint, heavily soaked in
cod-liver oil, was applied widely over the part to be
treated, and was taken off at the end of 12 hours.
With experience it has been found that once in 24
hours is sufficiently often to uncover the dressing,
which is now left in situ and re-soaked with cod-liver
oil, the lint not being taken from the skin surface until
the end of 48 hours—an obvious advantage where the
area to be treated is large.

Löhr and Winnett-Orr of Nebraska (THE
1933, ii., 357) use the occlusive method, but
occlusion that we have found necessary is
the dressing by jaconette, in an endeavour
the lint saturated. Crude cod-liver oil is
m the commencement in all cases. Where
ve not reacted previously to the ordinary
it has been found that cod-liver oil hastens
. and the speed with which an indolent area
formed into one of healthy granulation is
ble. The treatment too is popular. Almost

or resentment, and (hysterical) conversion symptoms were found; often all of these would be discoverable, and seldom less than four. Outstanding features were a preoccupation with discomforts, whether expressed in physical, mental, or social terms, a feeling of dissatisfaction or resentment in regard to them, and various expressions of anxiety; trembling was frequent. The complaints were commonly vague, but expressed with great earnestness, often also with rich prolixity and as though learnt off by heart. Sometimes these complaints verged on the bizarre—e.g., "when I eat the food it gets just here and it keeps on boiling and wind, and after my food this right leg of mine goes dead . . . . Like an acid it keeps on fermenting in my mouth. And the wind works round me here. And it goes dead, I got no feeling. And this fluid seems to work all through my body, this acid boiling up: all my food seems to go to it . . . . White stuff dries in my socks . . . . Then when the doctor stroked the soles of my feet, he struck the delicate spot and it ran all up my leg . . ."

A majority had a grievance against the pension authorities, the public assistance committee, medical boards, or society at large—"the capitalist system."
is was not expressed as a delusion but as a general

every patient has said that the first application of cod-liver oil has given much greater ease than other dressings. One case, which is not illustrated, may be quoted.

A marine fireman, who was scarred in almost every part of his body, was burnt on the left arm, shoulder to elbow,

FIG. 2.—Extensive burn from a fall into the fire similarly treated.

is more effective. But this means care and trouble and—dare it be said ?—intelligence. And, as I say, the question arises: is it worth while? After all, just as "life is more than meat and the body than raiment," so a bout of itching, even to the degree of suggesting the inquiry "what is the doctor doing about it?"—and most of the minor disturbances in life tend to raise the query in this soft age—may be a very mean payment for a good dinner, a cocktail or sherry party or the vanity of toilet powder and a fur boa. The position should be faced clearly and as clearly stated. Our function is to explain and guide, not to govern and control.

There are few cases of pruritus for which we cannot do a good deal and fewer still for which we cannot do something. I do not think there are any for which we can do nothing. The most intractable cases of all are those instances of diffuse itching which go by the depressing name of "senile pruritus." The use of this term stultifies our efforts at diagnosis, it does not add to our knowledge. In quite a number of these cases the patient is in many respects young, and not old, for his years, is of the alert and active type, and a close examination of his skin does n reveal evidence of that atrophy which is too g assumed to be present. On the other hand w quently see skins that are definitely atrophied, i older patients, with no such disability. statement, so frequently made, that the so-called senile pruritus a bled by " metabolism" is anothe n, unhel its very vagueness. panel doctor for an acute intestinal obstruction, and it was found that not only was there no scarring from the recent burns, but the brown pigmentation, which is so often left after this treatment, had entirely disappeared. Another case confirms this opinion.

A woman, aged 25, had been in hospital for more than two and a half years as the result of extensive burns caused through falling into the fire at home. She had been treated by varying methods over a period of two years, and extensive scarification had taken place to such an extent that her chin is pulled down at least 1½ in. towards the chest wall. In the areas where no actual healing had taken place skin grafts were attempted but did not take. Finally cod-liver oil was used on the sites where no healing had occurred, and we are now presented with a picture of islands of unscarred healthy skin lying in the middle of extensive scars.

Two cases of burns treated by Löhr's method from the onset may be briefly related.

A. B. (Fig. 1) was scalded over the whole of the left forearm to the second and third degrees by a pan of boiling fat, and was admitted to hospital on April 10th suffering intense pain. Dressed with cod-liver oil, he said the pain was at once relieved. He was discharged 14 days later without a vestige of a scar, and within a month the pigmentation had disappeared.

C. D., reputedly an epileptic, was admitted on April 15th and discharged on June 28th. His extensive burns were the result of a fall into the fire, and his progress under a cod-liver oil dressing may be traced in the photographs (Fig. 2). He was discharged with nothing but a dry dressing. No scarring followed even in so extensive a burn as this.

With such good results in burns, it was decided to try crude cod-liver oil as a dressing in other cases. Indolent ulcers and deep abrasions were so treated, but ing the rule "if there is pus, it must With this proviso cod-liver oil treatment und of advantage in a great number of areas. After the removal of pus or patches of skin, oil applied in the way s induced rapid granulation of tissue lolent in leg ulcers and even in fistulæ. stula had been in hospital 34 days under nent and still showed a slight serous ter packing the wound for six days with he patient was able to leave hospital, ed to make two out-patient attendances l of the dry dressings. Fig. 3 shows how ation is induced.

septic area on the leg for three weeks whilst tis and sloughing of the skin of the right foot l. He was in hospital 17 days under cod- eft almost entirely cured. On reporting one hing was to be seen of the wound save a mentation which disappeared in a few days.

There is distal and proximal surfaces of a joint are in local, no immobilisation is undertaken and no occlusion attempted except that obtained by a covering of aconette. Crude cod-liver oil is used and is applied by lint saturated therein. The dressing is not removed for 48 hours, but at the end of the first 24 hours—or more often if it seems necessary—it is re-soaked in situ with cod-liver oil. In certain cases at the end of a week the granulations are found to be exuberant; cod-liver oil dressing is then replaced for 24 hours by red lotion or a paste with a zinc base.

The only disadvantage of the treatment, as noted in your annotation, lies in the somewhat unpleasant smell from the dressing, but this can be mitigated by frequent change of bed linen. At one time we included an aromatic in the oil, but gave it up as it did not seem worth while. Sometimes the scent of the oil seems to make a patient less ready for his food, but this mild nausea soon passes away. The advantages are obvious: the ease which the patient obtains from the first dressing, the abolition of frequent change of dressings (with consequent pain and disturbance to the patient), and the almost total elimination of scar tissue. The brown pigmentation which is found on the healed skin clears up without further treatment.

A laboratory comparison was made between liquid paraffin and cod-liver oil, 10 c.cm. of either being inoculated with *Staph. pyogenes aureus*. In the case of cod-liver oil after 48 hours' incubation, subcultures on agar proved that although the organisms were still alive the growth was inhibited. The same result was obtained with liquid paraffin over a week. Obviously neither is a suitable medium for the growth of the organisms, and this will account (as Löhr reports) for the change of an unhealthy surface into the "clean ruddy picture of healing."

Whether the vitamin content in cod-liver oil has a natural affinity for the skin and the underlying tissues it is difficult to say, but there is obviously some factor in cod-liver oil which is not present in such oily dressings as liquid paraffin. This "something" has the effect of much more rapid healing and the almost entire elimination of scar tissue.

EASTERN HOSPITAL, HOMERTON.—Mr. Somerville Hastings recently opened the new isolation block erected by the London County Council at Eastern Hospital, Homerton. It is a two-storey building and provides accommodation for 60 patients in single-bedded wards.

NEUROSIS AND UNEMPLOYMENT

y Aubrey Lewis, M.D. Adelaide, M.R.C.P. Lond.

FIRST ASSISTANT MEDICAL OFFICER, MAUDSLEY HOSPITAL; CONSULTANT IN PSYCHOLOGICAL MEDICINE, BRITISH POSTGRADUATE MEDICAL SCHOOL, HAMMERSMITH

Much has been written about the "industrial euroses" that follow accidents for which compenation can be claimed, and about the "war neuroses" n which pensions play a part. The effects of nemployment upon the mental state have also een much spoken of in the last few years. There re, in short, gener [illegible] recognised conditions in hich social influen [illegible] to play an indispensable art in provoking [illegible] lness and so maintaining ocial incapacit [illegible] nce these social influences ct upon man [illegible] an the few who respond with neurosis, [illegible] portant to see what other predisposing factors are at work in these few, as well as the social and clinical *consequences of the* adverse circumstances.

A special group was available for such inquiry. A series of patients on out-relief had been seen in whom presumptive mental disorder, generally of a mild chronic kind, was associated with long periods of unemployment. They were referred to the Mile End Psychiatric Clinic by the local public assistance committees (P.A.C.) for an opinion as to diagnosis and treatment. Fifty-two successive male cases, so referred between May, 1931, and June, 1932, have been taken for study. They do not form a representative group of people on out-relief, nor perhaps even of those on out-relief who had been diagnosed as neurasthenic, for the process of referral was not a routine one but depended on selection of appropriate cases by the various district subcommittees of the P.A.C. In age they ranged from 20 to 67: seven were between 50 and 65, thirty-two between 35 and 50, thirteen between 20 and 35. The information about them was obtained by the following inquiries:—

1. A social history was obtained from a relative of each patient, prior to his attendance at the psychiatric clinic, by a psychiatric social worker.
2. The P.A.C. supplied details of medical history in most cases.
3. The psychiatrist examined the patients on one or more occasions and recorded the findings.
4. The case papers of the P.A.C. giving the whole history of the patients' relations with the administrators of out-relief, under the guardians' régime and that of the present P.A.C., were put at the disposal of the psychiatric social worker. The relieving officer who dealt with each case was interviewed in person.
5. In 49 of the 52 cases the psychiatric social worker visited the patient's home at a later date, saw him, his wife or a relative, and ascertained the subsequent happenings.

Only a brief account of the voluminous data accumulated can be given here. For them I am indebted to Miss M. A. Lane, the psychiatric social worker attached to the clinic, and to Miss Janet Galloway, who as research social worker at the Maudsley Hospital has studied the social aspects of this matter fully; her findings are being published elsewhere.

The Clinical Features

The clinical pattern was remarkably uniform. It was that of a chronic neurosis in which hysteria predominated. Various combinations of anxiety, irritability, hypochondria, depression, querulousness or resentment, and (hysterical) conversion symptoms were found; often all of these would be discoverable, and seldom less than four. Outstanding features were a preoccupation with discomforts, whether expressed in physical, mental, or social terms, a feeling of dissatisfaction or resentment in regard to them, and various expressions of anxiety; trembling was frequent. The complaints were commonly vague, but expressed with great earnestness, often also with rich prolixity and as though learnt off by heart. Sometimes these complaints verged on the bizarre—e.g., "when I eat the food it gets just here and it keeps on boiling and wind, and after my food this right leg of mine goes dead . . . . Like an acid it keeps on fermenting in my mouth. And the wind works round me here. And it goes dead, I got no feeling. And this fluid seems to work all through my body, this acid boiling up: all my food seems to go to it . . . . White stuff dries in my socks . . . . Then when the doctor stroked the soles of my feet, he struck the delicate spot and it ran all up my leg . . ."

A majority had a grievance against the pension authorities, the public assistance committee, medical boards, or society at large—"the capitalist system." This was not expressed as a delusion but as a general attitude of touchiness and resentment, which would perhaps be evoked in a previously friendly and deferential patient when one asked him what standard he had been in when he left school, whether he had a pension, what work he had been able to do in the last two years, whether he had used any form of contraception, and so on. In 17 of the patients this attitude was very evident, and had at some time led to more or less severe outbursts of rage or violence. Convinced assertions of victimisation, made in apparent calmness, were never obtained, and the patients showed, to express it in psychiatric terms, a paranoiac reactive development of personality, rather than a paranoid delusional formation.

Irritability was commonly complained of, or was reported by the patient's wife; it was always associated with some depression. Depression was observed and reported in 30 of the patients, but (like all the other symptoms mentioned) may well have been present, though at the time of examination unobstrusive, in many more. It rarely was extreme and in no instance was it associated with self-reproach or delusions. It is remarkable that in a few of the men it was apparently not the case that they were depressed; they were cheerful, in spite of the shaking and other discomforts, they slept and ate well, and their general manner suggested that they were content. It would of course be unwise to assume that these patients were happy or that their general mood differed greatly from that of many others who were said to be, or professed themselves, depressed, and who wept or looked glum—though unconvincingly—while reciting a catalogue of queer feelings and tremors.

The doubtless complicated and equivocally shown attitude of these men towards their situation and their symptoms cannot easily be expressed in simple affective terms, such as "depressed," and their affect was *not* so sweeping and unvarying as in the familiar psychiatric disorders of mood; it corresponded more to the instabilities of psychopathic personality. Anxiety was a common feature among the patients; in 28 it was conspicuous, and in almost all demonstrable. The modes of its manifestation varied; clear-cut anxiety attacks, not obviously occurring in terrifying situations, in which the somatic expressions were brief, widespread, and "classical"; or sweating, trembling, and dread before medical examination and other more or less important occasions; or constant restlessness and ill-defined apprehension occurred, as well as localised anxiety in which the activity of the heart or other organ was the centre of anxious preoccupation. Phobias—e.g., against crossing the street or riding on a bus—were not infrequent. Tremor was one of the most common findings; it was striking in 23 of the patients and was observed in most of the remainder; it was in many cases obvious to the casual glance—coarse, uneven, with jerkings or twitchings of the head and trunk as well as of the extremities; and in a large number it was the chief symptom complained of. Where it was a fine tremor other evidence of anxiety was present: where coarse or odd, less of general anxiety and more of interest in the symptom was the rule.

Three of the patients showed a mild pseudo-dementia, professing not to understand questions or giving inappropriate answers; they were unintelligent men who resented questioning, and their behaviour may perhaps be regarded as an intentional effort to mislead the examining physician. One patient had had a fugue, and he fell about when he walked: two others had a gross, anomalous stammer. These were all hysterical phenomena. Five of the patients were chronic schizophrenics, and 3 of these had been in mental hospitals: in none of them were the symptoms recent, the onset had been at least 7 years before: it is unnecessary to describe the symptoms they showed, which included affective incongruence, characteristic thought-disorder and paranoid hallucinations. There was one epileptic patient, and 6 in whom arterio-sclerotic changes were present and seemed contributory to some of the "mental" symptoms—e.g., lacrimose expressions of anxiety. In one patient a diagnosis of cortical degeneration, possibly of vascular origin or conforming to Pick's disease, was made.

Causal Factors

On a careful survey of the history of each of these patients, one could understand how the present illness had developed. This way of thought, however, can be deceptive since it ignores the alternative modes of response to those taken by the patient and is willing to leap over unknowns: it may be no more than fitting the data into one's preferred scheme of mechanisms and consequences. It is however the most satisfying and profitable way of regarding the individual case clinically. In distrust of this clinical approach, one may look for the common occurrence in these patients of presumptive causal factors, or to put it more correctly, for biographical data which characterise this group, and to some extent differentiate them from people with other illness, or from healthy people. Unfortunately, on many of the points investigated in this series, comparable data for the rest of the population are not at hand.

In this group, therefore, it was not so much the "causal" factors but rather the common peculiarities that were examined—these were concerned with social and medical facts and extended over more than the individual history of the patients.

THE FAMILY

The fathers of the patients had in 26 of the 45 known cases been unskilled workers; in these 26 the size of the family to which the patient belonged was nine children, whereas it was seven children in the 19 cases where the father had done skilled work. There were 7 instances in which a parent or sibling of the patient had been for years in a mental hospital: in these relatives schizophrenia, involutional melancholia, and mental defect were the diagnoses, while in all of these 7 patients themselves there was some departure from the clinical picture presented by the majority: in 1 there was extreme hypochondria of a bizarre sort, in another a paranoid psychosis, 2 were schizophrenic, 3 were mentally defective. It is very probable that the details obtained about the family history were incomplete, so that an appraisal of the findings might be misleading. The further information under this head is as follows: in 5 of the cases "nervousness" in one form or another (mostly anxiety states) was reported in parents or siblings: alcoholism in 7, in 3 asthma, in 4 epilepsy. In 8 patients, tuberculosis occurred in other members of the family. All these facts are probably underestimates. The parents of 4 of the patients had lived apart; 3 patients were brought up in an orphanage, and 1 who was illegitimate had been brought up by a foster mother; one of their parents had died during the childhood of 8 of the patients. The places of the patients in the order of births did not appear significant, collectively.

PREVIOUS EVIDENCE OF NEUROSIS

In 12 cases there had been in childhood neurotic traits, such as shyness, extreme sensitiveness, restlessness, somnambulism and day-wandering, unmanageableness, nail-biting, incontinence of urine and fæces, facial tic, and fits. During adolescence one had been delinquent, another had had fits. Serious ill-health in childhood appeared to have had a considerable influence on development in 3 cases. In 23 of the patients there had at some time been overt evidence of mental illness. Thus half the patients who had been in the army during the war were discharged with the diagnosis of shellshock, neurasthenia, or D.A.H.: almost all of these received pensions, for a time at least. Ten of the 25 non-army cases had shown some anomaly (epilepsy in 2 cases, delinquency in 2, neurosis after trauma in 3, and single instances of other disturbances). The physical health of the patients during adult life is considered below. In the work record and war service of these patients significant hints or plain evidence of neurosis appear.

OCCUPATIONAL HISTORY

Two thirds of the men were unskilled workers, a higher proportion than was found among claimants for unemployment benefit by the Ministry of Labour in 1925 (51 per cent.). In 11 of the cases the father had been skilled, the son was unskilled; in only 5 did the reverse hold true; in 7 both father and son were skilled.

Owing to the varied ages of the group, the facts about working life and duration of unemployment could not easily be compared. For various reasons it seemed best to estimate first the individual efficiency of each patient prior to his first post-war application for out-relief: 14 of the cases could not be so treated because of their youthfulness and brief period of industrial life. Of the remaining 38 there were 26 with satisfactory work records—i.e., they had held one job for seven years at least, or had not changed their jobs frequently without improvement of status. Seven of the 12 men who had unsatisfactory records in this respect had previously applied for out-relief (i.e., before the war), and the other 5 had aimlessly changed from job to job and might be called "feckless" or unsettled.

As there was a rapid increase in unemployment and dependence on out-relief in London between January, 1920, and January, 1923, with its peak in 1922, it might be supposed that extraneous factors d played a large part in bringing about the unemoyment of the group under consideration. Actually e highest number of them applying in any one year d so in 1920, before the difficulties had reached eir maximum. Of the total 52, 36 had applied for lief a year before the height of the out-relief figures r East Londoners as a whole had been reached.

In each case the reason for the application for ut-relief had been inability to support the family ecause of inadequate or no earnings. Actual illness nd particularly neurosis had not been given as the eason for loss of occupation. It must however be emarked that 36 of these 52 men had on one count r another previously shown some inadequacy: they ad been diagnosed as neurotic (24 cases) or as entally defective (3 cases) or had experienced he "pension situation"—i.e., had had some income, hich was not current earnings, in the form of war ension or pre-war out-relief. Nineteen of them uring their unemployment received National Health nsurance benefit for varying periods.

The amount of employment since the first appliation for out-relief is very little. Ten of these men ave been unemployed for ten or more years, 34 of hem have done no work lasting more than two veeks for the last five years or more. Half of them ad been completely idle for the four years before heir referral to the clinic, and only 6 had had more than a year's work during that time. One who showed mental defect, has never been employed at all. Eleven of the men have done no work for years except hop-picking in the autumn. The wives of 8 of them, incidentally, worked while their husbands were unemployed, but in only one instance was the work full-time.

WAR SERVICE

Just over half of these patients had been in the Army. Of the remainder, 10 were exempt because of their age, 4 were rejected as unfit, and 10 were either exempted or rejected on indefinite grounds. Of the 27 who were in the Army, 8 did not go overseas at all; 4 of them were discharged unfit soon after enlistment, and the rest were not called up until towards the end of the war. Nineteen saw active service; only 4 were discharged from the Army without any disability. Of the 19 on active service, 12 were awarded pensions, and so were 2 of the eight who were never sent abroad. Of the 14 pensions, 10 were for nervous disability, and 3 other men who did not receive pensions were similarly diagnosed neurotic on discharge from the Army.

It is evident that a large number of these men eligible for war service were either initially recognised as unfit to meet the stresses of war or later proved so.

PHYSICAL ILLNESSES

Physical illness had been recognised in 13 of these patients before their first post-war application for out-relief. In the individual cases the influence of this on general development seemed clear. Two of them had heart disease; in one case it was first diagnosed in adolescence, and in the other it has since brought about the patient's death. Two had had attacks alleged to be epileptic; others were tuberculous or had sustained injuries or were defective in some respect—e.g., crippled.

As the pension or compensation situation has so many analogies with out-relief in its possible deleterious effects upon personality and mental health, it is worth noting that besides those with Army pensions, 6 of these men have received compensation for injuries sustained since the war. Machine accidents to their hands and accidental falls had resulted in the receipt of a lump sum: in all these men neurotic symptoms had been evident before the happening, and probably they were more prone to accidents than is usual. Another patient injured one eye so that it had to be removed in 1930, at the age of 48: impaired vision in the remaining eye made work impossible. It is only since then that he has shown definite neurotic symptoms; he claimed but did not receive any compensation or insurance. Two other patients received compensation for injuries sustained by their children.

One of the patients when examined at the psychiatric clinic showed a presenile cortical degeneration; in 7 circulatory disorder (arterio-sclerosis in 5) was found responsible for some of their incapacity. Dental carries, pyorrhœa and arthritis were recorded in isolated instances.

It has often been said that the repeated medical examination of hysterical patients fosters symptoms. No clear connexion between previous examination and any particular symptom could be demonstrated in this group, though 4 of them quoted gloomy prognostications by consultants who had seen them, and many recited their symptoms with a readiness and uniformity of iteration that bespoke practice, and perhaps also iatrogenic acceptance of their incapacity.

Intelligence

Careful psychological tests were not practicable: information was drawn from the alleged standard reached at school and from the psychiatric observations made at the clinic. The school record could not be verified, unfortunately, as the necessary official documents had not been preserved except for special schools. The following numbers may therefore be taken as minimal. Of the 52, 3 had attended special schools for the mentally defective, 13 others had not reached Standard 5 at school. On psychiatric examination 8 men were recognised as definitely defective in some degree: they had none of them been to school in the period subsequent to the passing of the 1913 Act, as had the 3 who were certified defective; if they had, several of them would probably have been certified. At the other end of the scale, 3 of the men were said to have won scholarships at the elementary school; none of them, however, had continued at school till sixteen; they had all done skilled work prior to the loss of their employment (engineer, grocer, petty officer). Only 12 men however had definitely reached Standard 7 or Ex. 7 by the age of fourteen. The proportion of people of poor intelligence here is higher than for the average population: the figures are, however, too small and incomplete.

Marital State and Children

All but 9 of the men are married. Their average age on marrying was 25½ years—i.e., two years less than Beveridge's figure for the general population. Eight were married before twenty, 18 between twenty and twenty-five, 10 between twenty-five and thirty. In 4, the marriage was definitely a failure (desertion cruelty, separation by consent). One could not be, sure whether others got on well together: in the majority it appeared to be tolerably so: many of the wives showed loyalty and affection, sometimes against heavy odds. The offspring of the 43 marriages numbered 221, of whom 182 survived. Well over a third of the children had been born since the first post-war application for out-relief. Of all the marriages, in only 16 cases had there been no addition to the family since going on out-relief. There were 8 instances where four or more children had been born after the patient had gone on out-relief;

objections to contraception here played a large part, as 4 of the men in question were Roman Catholics and others expressed their dislike of any precautions. The average number of children was six for men over forty, and four for men under forty. The unskilled had larger families than the skilled. The proportion is the same as was found for the previous generation of these families and shows also the fall in the birth-rate: the average figures for size of sibship to which the patient belonged were 6·8 for the skilled, 9·3 for the unskilled: the corresponding figures for his own progeny were 4 and 5·7. An eighth of the surviving children, belonging to sixteen families, have abnormalities, thus 7 are certified as mentally defective, 7 have neurotic habits (e.g., enuresis), 4 have chorea, and 2 are tuberculous. On the other hand 9 children, belonging to seven families, have won L.C.C. scholarships for secondary or central schools.

Of the 43 married men 40 have dependent children. This figure has been compared with those given in the New Survey of London Life and Labour, and with others specially collected for this purpose from 150 married men, depending on public assistance, who were attending an East London non-residential training centre in the spring of 1933. Making necessary allowances for differences in age distribution (for the majority of the non-neurotic married unemployed were ten years younger than the married neurotic men under consideration) it appeared that the number of dependent children was higher for the neurotic group than for other unemployed. (The figures are given in Miss Galloway's paper.)

Social Conditions: Housing, Food

It is not difficult in individual cases to see how neurosis and unsatisfactory housing conditions may interact, aggravating or maintaining each other. To generalise would, however, be unjustified. The general facts as to housing are that the men formerly in skilled trades now live in poorer quarters than they would if working. The overcrowding among these patients is greater than for the average population in these districts: the comparable figures were obtained from the London Survey (Eastern Area) and for details Miss Galloway's paper may be consulted. The conditions under which they live seemed in many instances conducive to ill-health. As regards food, the outstanding observation was that the standards varied over a wide range among families with comparable allowances, the determining factor being apparently the care and intelligence with which the family money was laid out on food and other necessities.

Treatment and Outcome

Psychotherapy, treatment directed mainly at physical illness, and occupation were the measures employed. They were recommended according to individual needs, on grounds which need not be particularised except as regards occupation. The mentally defective patients, the schizophrenic and epileptic were dealt with appropriately. Of the various therapeutic recommendations none was so frequently made as that of occupation. In 41 of the patients it seemed to the psychiatrist that regular occupation, such as might be obtained at a non-residential training centre, would be of benefit. This rested mainly on two assumptions: (1) that most of their present symptoms were responses to lack of occupation, and (2) that appropriate occupation is beneficial for most varieties of mental disorder, including that which these men showed. It was recognised, however, that there were practical as well as theoretical objections. Training centres are intended in the first instance for the more promising and healthy man, who has a greater claim upon them than the weakling who has inherent deficiencies of personality and adaptation. The opportunities for the neurotic men were therefore fewer, even if they were eager to avail themselves of them. But they had in the course of years come to have an overtly or subtly hostile attitude towards occupation in general and towards the training centres in particular which could more easily be understood on psychological lines than reversed by psychological treatment. It was therefore impossible to ensure that one's recommendations about occupation would in all cases be carried out: actually they were in more than a third of the cases.

It is difficult to estimate the benefit derived from the various forms of treatment, which were in many cases combined in the one patient. The most satisfactory criterion of improvement seemed the subsequent work-record. It was found on inquiry a year later that just over a third of the men had ceased to be recipients of out-relief, mostly because they had obtained work, and of the others, 5 had had intervals of remunerative work. It must be remembered that the remainder who had not been working included mentally defective, epileptic, insane, elderly, and physically unfit persons. It is of importance also to bear in mind the persistently adverse factors against employment. Many of these men are such as in the London Survey are designated "on the fringe of unemployability" and are held likely to get continuous work only in times of prosperity or expanding trade in their particular line. It was impossible to get from the patients or their wives useful indications of whether or not there had been improvement in symptoms and well-being.

Conclusions

These men are as much social as medical problems. The majority of them are evidently unable to support themselves; the grounds for this are not to be found only in the economic circumstances which are responsible for unemployment in the country as a whole. Their previous history and present state are evidence of inherent deficiencies of adaptation to their environment. In their present circumstances may be seen a continuation of the external factors which for the greater part of their lives have interacted with inherited predispositions to make them in various ways unsatisfactory. It is not from them that one can judge what effect long continued unemployment has on mental health: a series of men previously stable and well adapted must be examined if one would test and amplify the almost universal impression as to the harm it does. The group here dealt with had been selected because of mental deficiency or disorder of some sort which was associated with unemployment, and often indeed its chief cause. Their disability could usually be interpreted along the customary psychological lines, if one assumed a constitutional bias towards neurosis. As far as psychopathology was concerned, there was nothing to distinguish them from other patients, in every class and walk of life, who showed hysterical symptoms, anxiety, and irritability. The group was not quite homogeneous as to clinical picture, but if one excepted the few defective, epileptic, and insane patients, there was a considerable uniformity in it, and a close likeness to the syndrome of the chronic "compensation or pension-neurosis." It would seem that just as in mental hospitals where there was little occupation schizophrenic patients would tend to lose individual ifferences and outwardly approximate to a few ommon types, so persons with hysterical or other ypes of inadequacy tend, when long unemployed, o exhibit tremors, giddiness, anxiety, hypochondria, esentment, and depression as a fairly characteristic yndrome. They cannot by any means be taken as representative of the unemployed population. Whereas in the latter extraneous factors are mainly responsible for the unemployment, in the group here reported the prevailing economic difficulties seemed only contributory and, in some cases, negligible causes of their lack of work.

Deliberate prophylaxis of such disorders, whether it be genetic or individual, must wait on a better knowledge than we have at present of the essential factors in the causation of neurosis: very likely this end is served to some extent by the now widely available treatment of disorders of behaviour in children, and would be served also by measures of negative eugenics inculcated into, and observed by, psychopathic persons. However this may be, when one is confronted with such patients as these, treatment must be undertaken. It is almost impossible, when seeing these men or studying their individual histories, not to be impressed by the need for early recognition and treatment of their difficulties, before they have become inveterate, and by the need for controlled occupational therapy. Regular occupation with trained supervisors seems the most important requirement for their recovery: if conjoined with psychotherapy it is much more effective, but psychotherapy without regular occupation achieves little. Such a requirement may seem ideal, but it is already available for similar cases at the colony conducted by the Ex-Service Welfare Association, where its value has been proved. The problem of unemployment through neurosis is of course much larger than this, in which one has been considering only men on out-relief; the cost—and the gain—of providing adequate treatment cannot be assessed. But for such men as are here considered, the situation is narrower and simpler. The earlier they are given occupational therapy, with some measure of psychotherapy, the less unfit will they be to cope with their circumstances and the more likely to become socially self-sufficient.

SOME INTERRELATIONS BETWEEN
WATER AND FAT METABOLISM IN RELATION TO DISTURBED LIVER FUNCTION

By H. Selye, M.D., Ph.D.

D. L. Thomson, B.Sc., Ph.D.
ASSOCIATE PROFESSOR OF BIOCHEMISTRY

Since the "fatty liver" is a very important problem both for the clinician and the experimental pathologist working on questions of general metabolism we attempted to find a simple and rapid procedure by which such livers may be obtained in one of our most common laboratory animals, the rat.

A partial hepatectomy, in which 70 per cent. of the liver is removed according to the technique described in a previous paper, initiates compensatory hypertrophy of the remaining lobes but no fatty degeneration. Such animals, even though their general appearance is quite normal, remain in a state of hepatic insufficiency for some time; this was proved by the observation that the detoxication of such anæsthetics as Avertin, which are inactivated by the liver, proceeds at a very slow rate in these animals, while other anæsthetics, like magnesium salts, which are not detoxified by the liver, do not lead to longer anæsthesia after partial hepatectomy than otherwise.[1]

In a recent experimental investigation, designed to study the effect of the liver on diuresis, we availed ourselves of this method for the production of a state of partial hepatic insufficiency. (In all our experiments we used adult male rats weighing approximately 200–250 g.)

I.—In the first group 6 normal rats were slowly injected intravenously with an amount of an isotonic solution of sodium chloride equal to 10 per cent. of the body-weight. Their urine output during the first four hours following the injections averaged 12 c.cm., varying from 10 to 16 c.cm. Laparotomies performed at this time showed that no ascites or visible tissue œdema had formed under the influence of the injections. The urine output at the end of 24 hours following the injections averaged 24 c.cm., varying from 22 to 32 c.cm. At this time the animals were killed; they showed no ascites or œdema; the liver and thymus were of normal appearance.

II.—The second group consisted of 6 rats partially hepatectomised and then injected with the same amount of saline as the animals of Group I. The average urine output during the first four hours was 1·5 c.cm., varying from 0·7 to 2·5 c.cm., and the total output during the 24 hours following injections averaged 10 c.cm., varying from 2·2 to 14·5 c.cm. Laparotomy 4 hours after injection showed marked œdema, particularly of the pancreas and of the retroperitoneal tissue. At autopsy, 24 hours after injection, the tissue œdema was still very marked. The thymus was dark red and very œdematous in all these cases, and showed marked venous hyperæmia and numerous "Mastzellen" in its stroma upon histological examination. The livers of these animals showed marked signs of fatty infiltration, both macro- and microscopically. Frozen sections stained with Sudan III. showed that the fat granules were more or less uniformly spread over the whole lobule and had no focal distribution. The nuclei revealed no signs of degeneration.

III.—The third group consisted of 6 rats partially hepatectomised and injected with saline in the same manner as in Group II. The only difference was that the partial hepatectomy was performed 48 hours previous to the injection. Histological examination shows that 48 hours after partial hepatectomy active mitotic regeneration of the residual liver tissue is already well under way. At this time the ability to excrete water is also regained since these animals eliminated 16 c.cm. (variations from 13·5 to 22 c.cm.) of urine during the first four hours and 35 c.cm. (variations from 28 to 40 c.cm.) during the 24 hours following the injection and showed no œdema or thymus changes at any time during the experiment. Their livers were not fatty.

IV.—In the fourth group we followed the urine excretion of 6 partially hepatectomised and otherwise untreated rats and found that they excreted only 0·4 c.cm. (variations from 0·25 to 0·5 c.cm.) of urine during the first four hours after operation, and 6·2 c.cm. (variations from 4·2 to 10·5 c.cm.) during the 24 hours following hepatectomy. They showed no œdema or ascites at any time and their livers disclosed only very slight degrees of fat deposition after 24 hours. The thymus was normal in all these cases.

V.—In the fifth group, also consisting of 6 rats partially hepatectomised, we removed 5 c.cm. of blood through

an injection needle inserted into the heart through the left jugular vein. The average urine excretion after 4 hours was 0·5 c.cm. (variations from 0 to 0·7 c.cm.) and after 24 hours 10·2 c.cm. (variations from 11·8 to 13·0 c.cm.). They never showed œdema nor ascites nor any thymus changes. Their liver was always markedly fatty. Six controls to this group showed that the removal of the same amount of blood does not produce fatty changes in the livers of normal rats with intact livers.

VI.—In order to see whether the tissue œdema and the thymus changes observed in Group II. were simply a result of the inability of such animals to excrete water, we performed bilateral nephrectomies on 6 rats and injected them with the same amount of saline as the animals of Group II. received. Four hours after injection they all showed much ascites but no trace of visible tissue œdema. Before the 24 hours were over, 3 of them died with severe ascites and such large quantities of pleural water accumulation that death was caused by lung atelectasis. The remaining 3 were sacrificed and also showed marked peritoneal and pleural water accumulations, but no pancreas œdema, and only slight thymus œdema. It seems obvious therefore that the tissue œdema observed after partial hepatectomy is not simply the result of defective water elimination.

We see that after partial hepatectomy the liver remnant shows marked fatty changes if the animals are bled or injected with large quantities of saline. In another series of 6 rats we were able to establish that the liver remnants show conspicuous fatty changes if the drinking-water be withdrawn from the animals after the operation. It appears therefore that any interference with water metabolism exerts a great strain on the relatively small liver remnant and causes fatty changes.

Since the removal of the hypophysis inhibits the fat deposition which is otherwise observed after pancreatectomy in the dog, we were interested to see whether it would also prevent the production of fatty livers under the conditions of the above experiments.

VII.—Seven rats, hypophysectomised months before the present experiments, were partially hepatectomised, and water was then withheld from them. They were killed 24 hours after hepatectomy, at which time only one of the seven showed a fatty liver and this one proved to be a partial hypophysectomy, in which the remaining piece of pituitary tissue sufficed to prevent adrenal and testicular atrophy.

This experiment suggests that the pituitary is essential for the deposition of fat in the liver. We wish to mention, in this connexion, that in 8 other rats, partially hepatectomised and hypophysectomised in one session, fatty degeneration of the liver remnants was not prevented. We deemed it possible that the inhibition of the fatty changes would not be observed until the adrenal atrophy developed.

VIII.—Six rats hepatectomised and deprived of water 24 hours after adrenalectomy seemed to confirm this view, since none of them showed fatty liver changes.

We feel that many more experiments will have to be done in order to clarify these strange interrelations between water and fat metabolism and the influence of the liver and of pituitary and adrenal hormones on them. In the present communication we merely wish to point out that such interrelations do exist. Experiments now under way in this laboratory are particularly designed to study the chemical aspects of this problem. The accompanying Table summarises our results.

COLOSTOMY AND ITS INHERENT DIFFICULTIES

A SUGGESTED OPERATIVE TECHNIQUE

By Turner Warwick, M.B. Camb., F.R.C.S. Eng.
SURGEON TO OUT-PATIENTS WITH CHARGE OF RECTAL CLINIC, MIDDLESEX HOSPITAL, LONDON

Although the technique of colostomy has passed through three distinct phases, the ordinary procedure adopted in the operation to-day differs in no way from that followed by Duret [1] in 1793 in the first recorded successful case of sigmoid colostomy. Great interest was taken in this procedure, and in France it became known as the method of Littre,[2] who, as far as records carry us, was the first to suggest (1710) that this method of dealing with certain cases of imperforate anus might be possible in the future. As far as we know Littre made no attempt himself to carry out this suggestion.

The first deliberate formation of an artificial anus of which we have record, was made by Pillore [3] of Rouen in 1776, who, however, "chose the cæcum as that part of the intestine which was most fitting to fulfil my object," both by its situation, and because it would act as a reseroir and we should thus avoid a continuous and involuntary lischarge of excrements."

Callisen [4] of Copenhagen and Duret of Brest, investiated in the post-mortem room the possibilities of a lumbar olostomy, but each found that he had opened the perioneum in performing the operation, and accordingly ejected this route. Duret's observation on lumbar olostomy took place in 1793; the date of Callisen's bservation is not definitely known, but it is believed to be prior to that of Duret.

The situation as regards colostomy in 1797 is fortunately very clearly outlined for us by discussions [5] aroused in the Sociétés de Santé of Paris and Lyon following a timely paper by Dumas [6] of Montpellier, Observations and Reflections on Imperforate Anus.

In the first phase of colostomy, which lasted nearly fifty years after Duret's successful operation, Littre's method was used, and during that time the procedure was applied to a limited number of cases. The results in these cases were so unsatisfactory on the whole, the danger of interfering with the peritoneal cavity being as yet unsurmounted, that Amussat in 1838 dared not employ this remedy in the case of Prof. Broussais, who died of carcinoma of the rectum. Subsequent reflection on the subject impelled Amussat [7] to reinvestigate the possibility of lumbar colostomy. He found that it was possible to carry out this operation without opening the peritoneal cavity, especially when the bowel was distended as in obstruction, or was artificially blown up. He developed the technique and produced such good results as far as immediate mortality was concerned, that his operation came into general use and remained so during the greater part of the 19th century. With the introduction of asepsis and anæsthesia in surgery, a return was gradually made to the abdominal route now employed.

During the first phase a mesocolic stitch was not infrequently used, so that a satisfactory spur often resulted, although the importance of the stitch with relation to the spur had not been fully appreciated. A mesenteric stitch was the recognised procedure in cases of gangrenous hernia, being inserted to prevent the opened bowel from slipping back into the peritoneal cavity. Indeed, the spur most useful in colostomy proved most refractory in preventing the closure of the "anus contre-nature" developing from this delayed treatment of hernia. The problem of its treatment was finally solved by Dupuytren [8] in 1816, when he introduced his spur crusher, which still forms part of the equipment of every theatre and is used in the restoration of continuity of the colon after a temporary colostomy, or after a Paul's operation. In the second phase, with the lumbar colostomy, it was only possible to attach the bowel wall to the lips of the wound, so that a satisfactory spur was not obtained. Thus, in the third phase, with the return to the abdominal route, the importance of the mesocolic stitch was not definitely established, so that an unsatisfactory spur was a very frequent complication until Allingham Junr.[9] reintroduced the stitch as an essential step in the procedure.

One outstanding lesson to be learned from a review of the literature of the subject is the great inherent antipathy to this remedy. This is perhaps largely attributable to the miseries of the uncontrollable and inaccessible lumbar colostomy and to the prejudice handed down from that time.

As we have noted, the present-day operation is fundamentally the same as in 1793, and yet, by care in the performance, in the after-treatment, and in the training of the patient in the management of the colostomy, surgery has made tremendous progress in overcoming its disadvantages. So much so that a surgeon performing large numbers of colostomies may feel some surprise when he finds a patient whose prejudices persist after full explanation.

And yet the results are not so invariably good that they can be expected to overcome this prejudice entirely. Occasionally a patient is so comfortable with a colostomy that he is not prepared to submit to the small risk of closure even if advised to have this done. Frequently [2] a patient is so thankful to have escaped previous miseries that he rests content with a colostomy when he understands there is no escape from it. It may be assumed that in such cases the colostomy is well-behaved, that it requires little attention, and that the patient is so placed that what attention it does require is well within his power to give.

A considerable number of patients with colostomy, however, are far from content. These may be divided into two classes: (1) Those who are so placed that a colostomy life is possible if the colostomy is satisfactory. (2) Those who are so placed that the necessity for colostomy is almost inevitably a tragedy.

In the first group much may be done to relieve discontent by a suitable refurbishing of an unsatisfactory colostomy. The second group consists for the most part of men engaged in manual labour. In women doing housework it is generally possible whatever their status to arrange matters, but to a manual worker living in a congested area and working under the crude sanitary arrangements provided for some workmen during work hours, the prospect is unfaceable.

Inasmuch as the surgery of one generation may have found inexpedient a procedure quite practicable in the next, it is periodically necessary to review two questions, firstly, how the number of cases left with colostomy may be diminished, and secondly, how the technique and after-treatment may be improved to give a lower percentage of cripples and malcontents.

With regard to the first of these, many of these colostomies have been performed for cancer, some inoperable, others operable but involving the lower third of the pelvic colon down to the anus. Can any form of operation which will avoid colostomy be introduced with comparative safety with more careful selection in cases of low sigmoid or high rectal carcinoma? This question must exercise the minds of many who have reached the stage where the power to perform the accepted operations smoothly and confidently need no longer be regarded as the height of achievement. This matter is, however, outside the scope of this paper, the object of which is to deal with the second question.

It is proposed to consider here the best site for an artificial anus, the commonest ways in which such an anus becomes unsatisfactory, and to suggest a technique by which unnecessary defects may be avoided as far as possible.

THE SITE

A colostomy may be either terminal or subterminal. The terminal variety seldom has complications if reasonable care is taken in its construction, but the subterminal or loop colostomy is not infrequently far from satisfactory. For this reason some surgeons have tried the device of dividing the bowel, closing the distal end and dropping it back into the abdomen, so as to be able to use the proximal end as a terminal colostomy. This has the disadvantage of burying in the abdomen a partially obstructed and therefore probably infected loop of bowel. It is certain that the difficulties of the subterminal colostomy cannot be solved thus. If the bowel is divided the distal portion should most certainly be accessible for any washing out that may be necessary.

As noted above, the lumbar route was chosen in pre-antiseptic days because it gave access to the ascending and descending colon—usually the latter—which have no mesentery and could therefore be opened without peritoneal soiling, especially when the bowel was distended. Nowadays this site has nothing to recommend it. The operation is comparatively difficult to perform, a spur cannot be reckoned on, and the inaccessibility of the stoma for washouts and cleansing makes it intolerable from the patient's point of view.

As to general site then everyone is now agreed that if there is no possibility of retaining a controllable anus in the natural position, it is necessary to fashion an artificial, reasonably controllable one in an accessible situation. An abdominal colostomy is the only one that fulfils these conditions.

There is still some lack of unanimity as to the most suitable position for the sigmoid colostomy. The direct routes for the cæcum and the sigmoid lie through the right and left iliac fossæ. For the transverse colon the choice commonly falls on a muscle-splitting incision through the rectus. Indeed, so satisfactory has control by the rectus proved that this route has seemed to many surgeons in this country to be preferable even in the case of sigmoid colostomy. Recently, however, it has become more usual to adopt the obvious approach in each case.

The following reasons favour the inguinal route for sigmoid colostomy.

The opening is nearer the flank. It is therefore easier to close off completely the peritoneal space lateral to it and thus prevent all possibility of internal hernia here. It is further from any future mid-line incision. It is nearer the pelvis, so that if a purely perineal excision is performed subsequently there is less possibility of drag on the pelvic colon, and if the combined perineal and abdominal operation is performed, the bowel below the colostomy and the gap in the peritoneum can be more easily dealt with. Apart from these secondary considerations the layers of the abdominal wall in the left iliac fossa afford practical advantages for the actual colostomy.

In the muscle-splitting operation through the left iliac fossa the following demonstration of its advantage may be made during operation. A split is made through the aponeurosis of the external oblique and another is made in the deep muscles with its centre opposite the centre of the split in the external oblique. If the patient is now made or allowed to strain during the anæsthetic the hole in the deeper layer tends to be drawn laterally and sometimes quite clear of the split in the external oblique.

During strain, then, it may be argued that in an inguinal colostomy the gut traversing the muscle-splitting incision tends to be distorted as well as compressed, and an additional supporting factor is provided. The extent of this distortion varies with the distance externally from the rectus sheath.

In the incision through the rectus the hole through the abdominal parietes is compressed during coughing or straining but remains undistorted. This variety relies on muscular contraction, which in a carefully planned incision usually gives adequate control during straining.

FAULTY RESULTS

The method in which the colostomy is performed is of the greatest importance. There is no doubt that the simplest colostomy—an incision through the parietes just adequate for the loop to lie comfortably in each layer, with the loop held in position with a glass rod, and the bowel wall and skin so trimmed that the double-barrelled effect is not hooded by bowel wall or by skin—gives satisfactory results in the majority of cases, particularly if the operation area is properly supported after operation and no post-operative distension allowed to throw strain on this weakened part. In a recent paper Gabriel and Lloyd-Davies[10] survey the end-results of colostomy cases at St. Mark's Hospital and find that in 86 per cent. the function is satisfactory. These results are interesting inasmuch as the operations in this series have been performed by experts who have devoted considerable thought to the shortcomings of colostomies, and it may be assumed that the figures present a correspondingly favourable view of the end-results. A review of the results of colostomies throughout the country would probably be far more discouraging.

The following faults are the most common:—

1. *Retraction of spur.*—An essential of the satisfactory subterminal colostomy is the provision of a suitable mechanism for preventing fæces from entering the unused portion of the bowel. This mechanism may be furnished by the projection (spur) of the posterior wall of an incompletely divided bowel, or by some interposition of abdominal wall in a completely divided bowel. If the tissue intervening between the proximal and the distal stoma sinks below the surface of the skin, the mechanism fails, fæces pass into the distal stoma and further disability results from infection here, and possibly from fistula formation. In such cases the spur must be advanced, which may be a simple matter or may require an extensive repair of hernia.

2. *Stenosis.*—The tendency in a muscular aperture is to enlarge, especially under strain, but that of a skin opening is to contract, and stenosis of the skin in relation to colostomy is not uncommon. With stricture formation in the skin it may happen that the gut remains pouting, becomes œdematous and is obstructed in this way. More often as the skin contracts the bowel tends to recede into the subcutaneous layers. As the portion of bowel attached to the deep fascia remains more or less in situ, the intermediate portion pouches into the subcutaneous area, but such a pouch is of no disadvantage unless it is associated with skin stenosis.

In its worst form this stenosis with subcutaneous bulge may be regarded as a complication associated with simple rod colostomies that have been performed through inches of subcutaneous fat. The permanent spur is then only supported by a fibrous cord of scar tissue in the subcutaneous layer connected with the skin on both sides of the colostomy and passing through the mesentery where the rod lay. This support is somewhat inadequate in stout subjects, especially when the skin is tending to stenose around the stoma. The difficulty arises infrequently in thinner subjects, because the more closely the fibrous cord is related to the fascial external oblique the more stable the supporting mechanism.

This condition frequently calls for operation to remove the hood of skin, to enlarge the opening of the bowel and to stabilise the fibrous cord in relation to the deep fascia. The skin may be stitched to the deep fascia to prevent pouching. Owing to instability it is not infrequently associated with hernia and further treatment is necessitated for this.

3. *Hernia.*—In hernia during coughing and straining gut is flung en masse against a weakened portion of the fibromuscular wall which tends to give before it. The resulting bulge may be a small hemispherical one—when a little more of a loosely fixed colonic loop momentarily pushes through and recedes—or may be associated with a progressively enlarging pear-shaped hernial sac, similar to that in an ordinary incisional hernia.

4. *Prolapse.*—The causative factors in prolapse are accessory to those of hernia. In hernia the gut is flung en masse at the weak area during straining and coughing, but for a prolapse to result from such a strain it must happen that the colon adjoining the proximal or distal orifice is projected or forced end-on at a lax stoma, through which it protrudes. This obviously can happen most easily when the distortive action of the deep muscular layers is absent as in a "through the rectus" incision, or where the hole has been so constructed that the fibromuscular walls are very loosely apposed to the colostomy loop. This poor apposition of the fibromuscular layers means, therefore, that a potential hernia is present. In addition, the bowel prolapsed must be part of a loose loop or it could not prolapse. It is advisable, therefore, in performing the operation to draw down fairly tightly the upper loop which most often prolapses, but this not infrequently leaves the lower one lax. Indeed, in performing a colostomy with a view to subsequent radical procedures it is advantageous to leave the lower one as free as possible. To compensate for this laxity the abdominal wall may be left surrounding the bowel more firmly in the lower compartment.

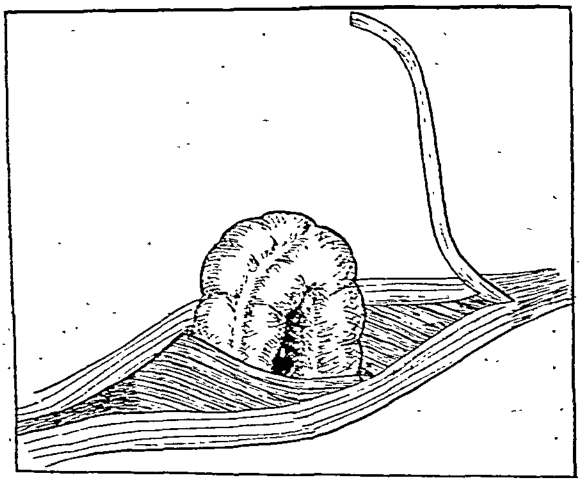

FIG. 1.—The deep muscles are supported with a silk suture.

Hernia, and also prolapse, are therefore best prevented by making the aperture in the abdominal parietes suitable in size from the beginning and preventing its enlargement. The hole should never take more than two fingers. It is unwise to attempt to enlarge for exploratory purposes the incision through which the bowel is to be brought for loop colostomy, in the belief that the hole can be satisfactorily reduced to the required size by careful resuture. Not only must the hole in the deep muscular layer not be made greater than is required for the actual colostomy, but also all possible measures must be taken to prevent it from stretching postoperatively.

The stress of a cough on a wound stitched up throughout its whole length is very small compared with that resulting when it is incompletely stitched so as to fit loosely around a loop of bowel. This loop becomes transformed in the act of straining into a wedge tending to increase the hole. Also favouring this increase a mild inflammatory process is likely to occur immediately after operation, sufficient to weaken the grip of the stitch partially closing such a wound, or to favour cutting-out. All precautions to ensure the resistance to herniation should be taken at the outset. If this resistance is adequate from the beginning all will remain well. If inadequate precautions are taken, the hole in the fibromuscular layer will undergo increase after operation, and at the end of convalescence there will be present an appreciable bulge which will tend to increase slowly with further activity. It must be remembered that all the surgeon has to do to increase the size of the opening obtained by muscle-splitting is to stretch further, and this stretching process is comparable to that which occurs under the force of coughing or straining.

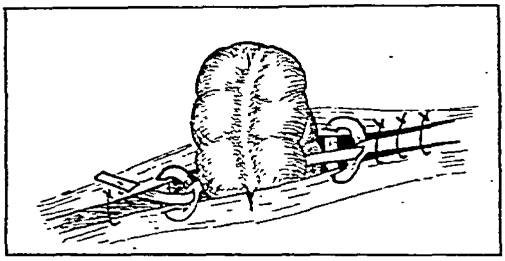

FIG. 2.—Method of suture of aponeurosis of external oblique.

SUGGESTED TECHNIQUE

The following technique is the one I have developed for use as a routine, after survey of the various possible methods. It aims at preserving the spur, preventing hernia, and diminishing the risk of prolapse.

A circular incision, diameter 1¼ in., is made by pulling up and shearing off the skin around a point 2 in. internal to and just above the anterior superior spine. This disc of skin and the underlying fat are removed and the aponeuroses of the external oblique exposed. The skin incision is enlarged up and down. A fascial strip just over ½ in. wide and 3½ in. long is then split off the external oblique. Externally, the strip is carried back parallel to the fibres as far as the muscle insertion, medially almost to the middle line (Fig. 1). Here it will be seen to consist of only one layer of the anterior rectal sheath. It is freed at its medial extremity. Retraction of skin is, of course, necessary in this procedure.

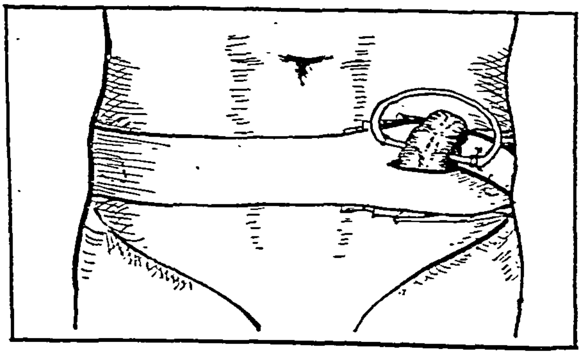

FIG. 3.—Strips of vaseline gauze surrounding colostomy are fixed by elastoplast strips carried round to back. The glass rod is stitched to the elastoplast. A second layer of vaseline gauze is now placed round the loop of bowel before this is opened transversely.

About the middle of the circular incision the deeper layers of the abdominal wall are then split for not more than 2 in. An incision admitting two fingers easily is made in the peritoneum.

The iliac or pelvic colon is sought and with due regard to the required tightness of the proximal loop a piece of tape is passed through the mesentery close to the bowel at a point suitable for colostomy. If the loop will not come up into the wound satisfactorily, the outer mesenteric fold and any adhesions reinforcing it are dissected up until there is no drag on the colon as it lies in the position required for colostomy.

The loop is returned to the abdominal cavity while further intra-abdominal examination is made. If considered advisable, a running suture is inserted to obliterate the peritoneal space outside the colostomy in which small gut might become trapped.

The colostomy loop is now withdrawn and the divided peritoneum approximated through the hole in the mesentery. The limits of the split in the deepest muscular layers are fixed with a No. 2 silk suture to prevent stretching here (Fig. 1). A Galley's needle is now applied to the fascial strip. It is carried through the edge of the divided external oblique at the selected point and locked, then through the mesentery, fixing the external oblique together on the inner side, locked and fixed there with silk (Fig. 2). Anterior and posterior to this locking suture the external oblique is sutured with catgut. Particular care is taken at the external angle of the rectus sheath. If either the upper or lower compartment of the hole through the external oblique appears tight, the lips may be notched until the desired size is reached. The lower compartment may be left tighter than the upper.

A rod is placed through the mesenteric hole superficial to the fascial strip, and the ends fixed by a complete loop of rubber tubing. In a very fat patient the rod and fascial strip should not both go through the same point in the mesentery unless the subcutaneous fat is excised over a wide surrounding area. In a fat patient the fat is stitched to the deep fascia to prevent the bowel bulging into the subcutaneous plane. The skin is then approximated round the bowel.

Two strips of vaseline or paraffin and flavine gauze are placed around the colostomy loop crossing under the rod on each side. If thought necessary, these are stitched to the skin at one or two points. The gauze is fixed in place by strips of elastoplast surrounding the wound, and these are carried round to the back as far as the lateral border of the erector spinæ on both sides to further support the weakened area. The glass rod is sutured to the surface of the elastoplast to prevent movement. The bowel is next covered with a layer of vaseline lint, a small hole is cut in this, and the bowel is opened transversely with a cautery. Any gross mass of fæces is removed. The stoma is covered with vaseline gauze. Delay in opening the stoma often results in a great measure of discomfort to the patient. On the following and subsequent days, the dressings may be taken down as far as the elastoplast, and at any time an ounce or more of paraffin may be injected into the proximal stoma through a catheter. Later, the colostomy is well trimmed back, as any redundant peritoneal covered bowel left exposed will recede into the subcutaneous area, tending to drag back the spur and also to form a pouch.

NOTE.—A similar technique is used for colostomy through the rectus sheath, the anterior sheath of which affords an excellent strip.

Repair of unsatisfactory colostomy.—In repair of a colostomy for hernia or retracted spur the fascial graft is also used.

The colostomy loop is freed from the skin and the layers of the abdominal wall are defined and freed from each other and from the peritoneum, which is not opened. The colostomy loop is now pulled forward together with the peritoneum, and cholecystectomy forceps are worked round the bowel. This can usually be done without opening the peritoneum. Through the hole a supporting fascial strip and a temporarily reinforcing rubber tube are to be passed. A fascial strip is taken from the external oblique on one or other side of the colostomy, if this seems suitable. If the hernia is large, the musculature weak, the external oblique will probably be unsuitable for a graft, and a long strip from the thigh is taken. The deep muscular layers of the abdominal wall are sutured closely round the loop. The fascial strip from the external oblique or from the thigh is then used to suture the external oblique and to reinforce the spur, as in the operation described above. The remaining procedure is as already outlined. If there is a bad degree of prolapse, it may be necessary to amputate this subsequently.

In developing this technique I used the fascial strip method first with the route through the rectus. I found it always adequate as regards spur maintenance, but occasionally slight hernial bulging developed, because the hole in the posterior rectus sheath tends to get bigger, and in one or two of these cases there was a slight tendency to prolapse. The use of the inguinal route combined with a stitch support of the deep layers is, however, most satisfactory.

The anatomy of this region lends itself readily to this method of dealing with the special mechanical difficulties that are inseparable from the establishment of a satisfactory abdominal anus. The fascial strip cross-ties and firmly supports the fibromuscular aperture in the diameter which is usually the widest and weakest, and no other form of suture affords the same measure of security. I have therefore ventured to put the method on record in the hope that some of the suggestions may be of service to those who have not yet standardised their technique to their own satisfaction.

Clinical and Laboratory Notes

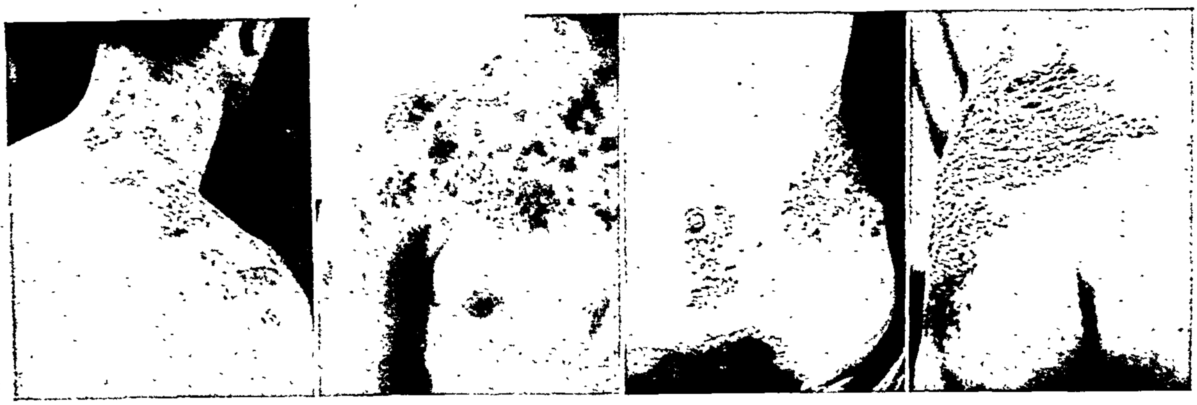
BILATERAL ZOSTER AND ZOSTER VARICELLOSUS

By P. W. Hutton, M.B. Camb.
HOUSE PHYSICIAN AT THE LONDON HOSPITAL

THE apparent rarity of bilateral zoster makes this case worthy of record.

A man, aged 21, a packer of wireless cabinets, attended the London Hospital with a typical zoster eruption of the right shoulder, left loin, and abdomen. Five days previously he had noticed irritation of his left buttock and loin. Shortly afterwards he noticed the eruption in this situation. The next day he noticed irritation of his right shoulder and a similar eruption appeared. At the same time scattered spots appeared over his trunk. He gave no history of previous illness and he had never had chicken-pox or zoster.

When he was first seen five days from the onset of the eruption, there were groups of vesicles and bullæ containing slightly turbid fluid grouped on an inflamed base in the areas of distribution of the right third, fourth, and fifth cervical nerve-roots and the left dorsal tenth, eleventh, twelfth and first and second lumbar nerve-roots as shown in the accompanying illustration. In addition he had a sparse eruption of scattered discrete pinhead vesicles on erythematous macules distributed on the back, chest, abdomen



Photographs showing the site of the zoster lesions.

and buttocks. All the vesicles were in the same phase of evolution and differed in this respect from the lesions of varicella. The right axillary and the left inguinal lymphatic glands were enlarged.

The patient's temperature was 100° F. and the pulse-rate 88. Physical examination revealed no abnormalities. The patient felt well and complained of no subjective symptoms except slight burning and irritation. He was treated in bed and given sodium iodide grs. 10 t.d.s. by the mouth. A dusting powder was applied to the vesicles. The vesicles rapidly dried up and he developed no post-herpetic pain.

Serum collected fourteen days after the onset of the eruption gave a positive complement-fixation reaction with a vesicular antigen from another case of zoster.

My thanks are due to Dr. W. J. O'Donovan for permission to publish this case and to Dr. R. T. Brain for the information about the complement-fixation reaction.

DYSOSTOSIS CLEIDOCRANIALIS

SHOWING UNIQUE SCAPULÆ OF PRIMITIVE TYPE *

By Victor J. Kinsella, F.R.C.S. Eng.

Dysostosis cleidocranialis is a developmental deficiency of the skeleton affecting chiefly the clavicles and the bones of the cranial vault. It is complementary to achondroplasia, in which the cartilage bones bear the brunt of the disorder.

Its interest lies firstly in its rarity. Although it was described as long ago as 1766, a careful review of the literature in 1908 by Hultkrantz revealed only 31 cases described clinically. There are a few other cases in which reference is made to either the clavicle or the skull alone. In the museums of the world there are only nine skulls showing the condition, five of these being in the institute of pathological anatomy of the University of Vienna. This institute contains also the skeletons of two cases—I believe the only two in existence. Efforts have been made by other institutions to obtain some of this material, but even in their days of tribulation, the Viennese preserve their sense of relative values and their museums retain their treasures.

The second source of interest is the light which this condition is said to throw upon the development of the clavicle, the first bone in the human body to ossify. In the embryonic clavicle, cartilage cells and afterwards osseous tissue make their appearance in a peculiar precartilaginous condensation of the mesenchyme. Seeing that in cleidocranial dysostosis the clavicle suffers along with the bones of the cranial vault, the clavicle itself has been looked upon as being partly a membrane bone. But as we shall see in the case which I am presenting, interference with growth in cleidocranial dysostosis may be found also in bones developed in cartilage—e.g., the scapulæ and phalanges of the foot.

A third point of interest is that the possible development of the clavicle in two parts complicates the attempt of morphologists to recognise in the human shoulder girdle the two ventral elements of the primitive pectoral girdle, the coracoid and precoracoid, which are seen in some of the lower animals, and which correspond with the pubis and ischium of the pelvic girdle. In the fruitless controversies over this question almost every possible combination has been made to represent the primitive elements from among the centres of ossification of the coracoid process, the clavicles, the metacromion, the suprasternal bones, and the various ligaments around the clavicle (costoclavicular, coracoclavicular and costocoracoid and the articular disc). Some morphologists

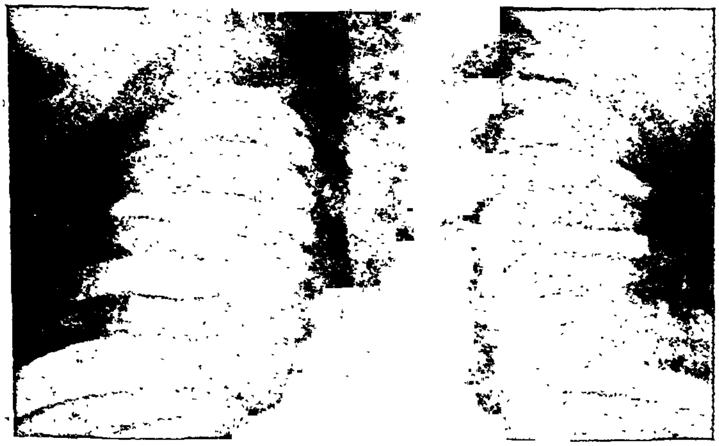


FIG. 1.—Radiogram of chest showing abnormality of clavicles.

---

* Communicated to the Royal Prince Alfred Hospital Medical Officers' Association, Sydney.

deny that the shoulder girdle has any pubic representative.

The patient who came under my care is a boy of 16 years. He is of slender build and with more than average intelligence, features noted by Paltauf in his case. His parents relate that the anterior fontanelle closed very late. In many cases a strong hereditary tendency has been noted, but clinical examination of the parents of this boy and X ray examination of their hands revealed no abnormality, and no relevant point could be elicited in the family history. A large number of the cases described are of French extraction, as was pointed out to me by Dr. Sear, but the parents of my patient knew of no French blood in their families.

The patient was almost able to approximate his shoulders across the front of his chest. On palpation absence of the acromial end of each clavicle was noted. The sternal ends tapered laterally to a point. These bones can be seen in the radiogram in the upper part of the lung field, and their radiographic density is much less than that of the ribs. They are no doubt very soft and deficient in lime salts (Fig. 1). From the under surface of the pointed extremities a thin cord passed laterally to the shoulder regions. Whether these cords were attached laterally to the coracoid or acromion or to some other part could not be definitely determined, but they probably represent the coracoclavicular ligaments (or thickened upper edge of the costocoracoid membrane). The clavicular parts of the deltoid and pectoralis major muscles were poorly, if at all, developed. The patient complained of no disability associated with the condition of his shoulder girdle; on the contrary, he played such games as tennis with ease. Absence of the acromial end of each clavicle, as described above, is the commonest type of clavicular abnormality met with in these cases. The next most common arrangement is replacement of the middle portion by a fibrous band which unites the acromial and sternal extremities.

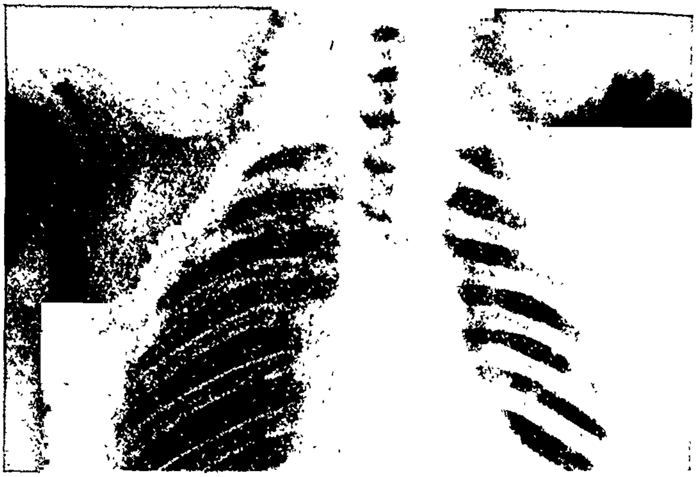

FIG. 2.—Radiogram showing abnormality of scapulæ.

Fig. 2 shows an apparent absence of the supraspinous fossæ of the scapulæ, the spine and acromion springing directly from the upper border, an arrangement rather similar to that found in the iguana and platypus. I cannot find reference to such a malformation in any other case. I am indebted to the director of the pathological anatomical institute of the University of Vienna for a personal communication, wherein he informs me that there is no such abnormality in the scapulæ of the two skeletons in the institute.

The skull in this patient shows the features usually described—a large cranial vault, small and narrow base, small facial bones, metopic suture, wormian bones in the neighbourhood of the lambda, high vaulting of the palate, and marked delay and irregularity in the eruption of the teeth. The erupted teeth were stunted and all were milk teeth, except three premolars and one canine. The remaining second teeth were still unerupted. The dental surgeon is at present exercised to provide an efficient masticatory apparatus, and proposes the removal of the erupted teeth and the use of prostheses. Dr. Sear has drawn my attention to an increased density along the suture lines in these radiograms, a feature already noted in cases seen by him.

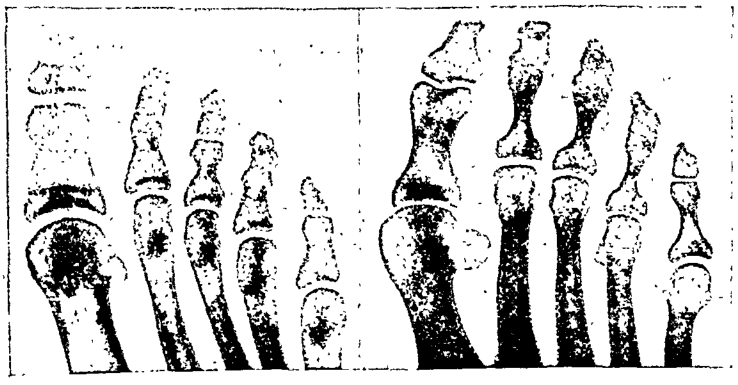

FIG. 3.—Radiogram of the patient's toes (left-hand photograph) compared with those of a normal person.

Radiograms of the toes are illustrated in Fig. 3 together with those of a normal person of about the same size but three years older than the patient. Note the shortening of the phalanges (already described by Murk Jansen) and the more open texture of the cancellous bone and deficient development of the compact bone. The phalanges of the hand show similar features in lesser degree. The index metacarpal is very long and shows an epiphysis at each end.

There were also noted a marked scoliosis, with lower limbs of equal length, bilateral cervical rib, club-feet corrected by operation in infancy, and changes in the pelvis. The narrowing of the pelvis, especially of the ilium, and the gap in the region of the symphysis pubis have already been noted, as by Paltauf.

For further accounts of cleidocranial dysostosis, and of the various speculative questions associated therewith, the reader may consult articles by Fitzwilliams[1] and Paltauf.[2]

PEPTIC ULCER IN A SOLOMON ISLAND NATIVE

By Clifford James, M.B. N.Z., F.R.C.S. Edin., D.T.M. & H.

It has been said that peptic ulcers are "confined to men of civilised races living in temperate climates,"[1] and the following case may therefore be of interest.

I had started medical work in a native-built hospital on Choiseul, the island lying at the north-western extremity of the British Solomons Group, and the most out-of-the-way of the larger islands. The latitude is 7° South, and the climate hot and moist. Organised fighting had ceased about ten years before. The wildest part of the island was on the Vurulata River, and from this region came my patient.

[3] Ogilvie, W. H.: THE LANCET, 1935, i., 419.

Qoqoro, a male native aged approximately 27 years, small in build, sturdy, but undernourished, was brought by his relatives because they said that he would die if left in his village. He was becoming thin. He himself said that he had pain in his abdomen, and "while his mouth wanted to eat his stomach would not let it eat." When he ate, it caused pain, and so he did not eat. Eating was followed by vomiting which gave relief.

On examination, he was obviously thin. He put one finger on a spot in the epigastrium to the left of the mid-line, and pressure there caused pain. It was quite localised. His spleen was enlarged to a point half way between the costal margin and the umbilicus, being due to malaria which is universal throughout the island. He also suffered from yaws as evidenced by the worm-eaten appearance of the soles of his feet; yaws also is universal. His mouth was red from the betel-nut which he was chewing, and his gums showed evidence of pyorrhœa which also is very common.

As malaria is the cause of most epigastric trouble in these parts, he was admitted to hospital and treated with quinine, and iron tonics. He received weekly injections of neoarsphenamine for his yaws. But while his malaria was much improved, and his yaws was cured, he still complained of his pain. A diagnosis of peptic ulcer was made. A mixture containing bismuth and sod. bicarb. relieved his pain, but considering the patient and his food and mode of life, a cure from medical treatment was not to be expected. The place we called the "theatre," and the staff consisting of one white nurse and one orderly, newly arrived from the bush, made surgical treatment also rather an unknown quantity.
